# **1.0 INTRODUCTION**

Stantec Consulting Ltd. (Stantec) has been retained by TC United Group to carry out a geotechnical investigation for a proposed residential development located on the properties at 27-31 Robinson Avenue in Ottawa, Ontario as shown on the Key Plan (refer to Drawing No. 1).

The geotechnical investigation was completed in order to determine the subsurface conditions at the site and to provide recommendations on the geotechnical design aspects of the project.

This report presents the results of the field investigation program and laboratory testing, as well as geotechnical design recommendations. Limitations associated with this report and its contents are provided in the Statement of General Conditions included in Appendix A.

# 2.0 SITE AND PROJECT DESCRIPTIONS

# 2.1 SITE AND PROJECT DESCRIPTIONS

The proposed development site contains three properties (27, 29 and 31 Robinson Avenue) that each currently contain an individual residential structure located in the south (front) portion of the property. The existing building at 27 Robinson Avenue contains a basement level while the buildings at 29 and 31 Robinson Avenue contain basements under parts of the structures.

Based on the information provided by TC United Group, Stantec understands that it is planned to combine the lots into a single property and construct a three-storey apartment building with a basement level. The building will encompass a plan area of approximately 630 m<sup>2</sup> and is planned to be constructed at the location shown on Drawing No. 1 in Appendix B. The Final Floor Elevations (FFEs) (tops of slab) are understood to be 58.85 m for the below-grade/basement level and 62.38 m for the first floor.

Based on a topographical plan of the site prepared by Stantec dated April 12, 2018, the ground surface within the site is generally flat with existing ground surface elevations varying between about 59.1 m and 60.5 m.

# 2.2 GEOLOGY

Available geological maps and previous nearby borehole records indicate that the subsurface conditions at the site consist of glacial till overlying shale bedrock of the Billings formation. Based on available subsurface information in the vicinity of the site including records of boreholes drilled by Stantec on properties on Robinson Avenue located approximately 30 m to the west of the site, the depth to bedrock is anticipated to be approximately 9 m to 10 m below ground surface.

# 3.0 INVESTIGATION METHODS

# 3.1 FIELD INVESTIGATION

Prior to commencing the field investigation, Stantec arranged for utility clearances to be completed by a private utility locating contractor, USL-1.

A geotechnical field investigation, consisting of advancing five (5) boreholes designated as BH18-1, BH18-2, BH18-3A, BH18-3B and BH18-4, was carried out on July 12, 2018. The approximate borehole locations are shown on the Borehole Location Plan (Drawing No. 1) in Appendix B.

The boreholes were drilled using a truck-mounted drill rig equipped with 200 mm diameter, hollow-stem augers with soil sampling capabilities that was supplied and operated by George Downing Estate Drilling Ltd. The subsurface stratigraphy encountered in each borehole was recorded in the field by a member of Stantec's geotechnical staff.

Soil samples were recovered at regular intervals using a 50-mm (outside diameter) split-tube sampler by conducting Standard Penetration Tests (SPTs) in accordance with the procedures outlined in ASTM specification D1586.

One of the boreholes (Borehole BH18-3A) encountered effective auger refusal on an inferred boulder at a depth of about 1.9 m below ground surface. Another borehole (BH18-3B) was, therefore, drilled approximately 1 m northwest of Borehole BH18-3A.

Dynamic Cone Penetration Testing (DCPT) was completed in BH18-4 in order to provide information on depth to bedrock. The DCPT encountered refusal at a depth of about 7.5 m below ground surface.

The locations and ground surface elevations at the boreholes were surveyed by Stantec field personnel and referenced to selected objects of known geodetic elevations interpolated from the topographical drawing of the site referenced earlier. The ground surface elevations at the borehole locations should be considered approximate only.

Details on the ground surface elevation and depth of drilling at each borehole are summarized in Table 3.1 below.

Borehole No.	Approximate Ground Elevation (m)	Total Depth Drilled (m)
BH18-1	59.5	8.2
BH18-2	59.4	5.9
BH18-3A	60.1	1.9
BH18-3B	60.1	7.5
BH18-4	60.1	7.5

Table 3.1: Summary of Borehole Details

A monitoring well was installed in Borehole BH18-3B. The monitoring well consisted of a 50 mm diameter PVC pipe with a 3.0 m long slotted pipe section. The well was backfilled with silica sand to approximately 0.3 m above the top of the screen and a bentonite plug was installed above the sand. The monitoring well installation details are provided on the Borehole Record for BH18-3B in Appendix D. All remaining boreholes were backfilled with drill cuttings mixed with bentonite.

All soil samples recovered from the boreholes were placed in moisture-proof bags. Soil samples collected during the investigation were returned to Stantec's Ottawa laboratory for detailed classification and testing.

# 3.2 LABORATORY TESTING

The following geotechnical laboratory testing was performed on selected samples:

- Moisture contents;
- Grain size distribution/hydrometer analyses; and
- Atterberg Limits.

Chemical analyses related to parameters associated with the potential for corrosion or sulphate attack (i.e. pH, resistivity, and chloride and sulphate content) were completed on one sample by Paracel Laboratories Inc.

The results of the laboratory tests are discussed in the text of this report and are provided on the Borehole Records in Appendix C. The results of the grain size distribution tests are also included in Appendix D.

Samples remaining after testing will be stored for a period of three (3) months after issuance of the final report. Samples will then be discarded after this period unless otherwise directed.

# 4.0 SUBSURFACE CONDITIONS

# 4.1 GENERAL

Detailed descriptions of the subsurface soil and groundwater conditions are presented on the Borehole Records provided in Appendix C. Documents providing explanations of the symbols and terms used on the borehole records are also provided in Appendix C. Laboratory test results are shown on the borehole records as well as Figures D1 and D2 in Appendix D.

The stratigraphic boundaries on the borehole records are inferred from non-continuous sampling and, therefore, represent transitions between soil types rather than exact boundaries between geological units. The borehole records depict conditions at the particular locations and at the particular times indicated. The subsurface soil and groundwater conditions will vary between boreholes and/or at locations away from the boreholes.

The information provided in the following sections is intended to summarize the conditions encountered; however, the borehole records provided in Appendix C should be used as the primary source of the subsurface information for the site.

In general, the subsurface stratigraphy encountered at the borehole locations consists of surficial materials including topsoil, asphalt and fill materials underlain by a native glacial till. A summary of the subsurface conditions encountered in the boreholes are provided in the following sections.

# 4.2 ASPHALT

Asphalt layers, measured to be about 50 mm and 75 mm in thickness, were encountered at the ground surface of Boreholes BH18-1 and BH18-2, respectively.

# 4.3 TOPSOIL

Topsoil was encountered in Boreholes BH18-3A and BH18-4. The thickness of the topsoil was determined to be approximately 0.2 m in both boreholes.

# 4.4 FILL

Fill materials of variable composition were encountered in Boreholes BH18-1 and BH18-2 (beneath the asphalt) and in Boreholes BH18-3A and BH18-4 beneath the topsoil.

The fill materials are comprised predominantly of silty sand with varying amounts of gravel and clay and contained rootlets. The fill was measured to extend to depths of approximately 0.5 m to 0.8 m below ground surface corresponding to elevations of approximately 58.7 m to 59.6 m.

Standard Penetration Test (SPT) penetration resistances of 3 to 15 blows per 0.3 m of penetration were measured within the fill materials indicating that these materials are in a very loose to compact state.

Laboratory testing conducted on samples of the fill measured natural moisture contents of between approximately 10% and 22%, expressed as a percentage of the dry weight of the soil.

# 4.5 GLACIAL TILL

A glacial till deposit was encountered below the fill materials and extended to the bottom of all boreholes. Based on manual/tactile examination of the till, the till consists predominantly of a sandy clay of low plasticity containing gravel. Zones of till comprised of silty sand with gravel were present between 6 m and 7m in Borehole BH18-3B and zones of sandy silt till were also encountered sporadically in the boreholes.

Borehole BH18-3A encountered refusal to auger penetration at a depth of approximately 1.9 m below ground surface on an inferred boulder and cobbles and boulders were inferred during drilling at other borehole locations. The glacial till in Ottawa is typically comprised of cobbles and boulders set in a matrix of finer-grained material (i.e. gravel, sand, silt and clay); larger boulders (e.g. in excess of 1.0 m) are common. The till is typically unsorted and without stratification, but in places contains discontinuous layers or irregular shaped masses of sand and silt. In this regard, where glacial till deposits are identified, cobbles and boulders will be present throughout the deposits and permeable layers of sand and/or silt may also randomly be present due to the unsorted and unstratified nature of the glacial till.

Standard Penetration Test (SPT) 'N' values measured in the glacial till ranged between 5 blows per 0.3 m penetration to spoon refusal of 50 blows per 0.1 m penetration. SPT 'N' values measured in the till within 3 m of ground surface were typically 15 or greater. An in situ shear vane test carried out at a depth of 4.3 m in BH18-3B measured an undrained shear strength of more than 110 kPa and a remoulded shear strength of 25 kPa. A vane test was attempted at a depth of about 4.4 m in BH18-1 but was not be completed as the vane could not be pushed into the soil.

Based on the results of the field testing and manual/tactile examination of the samples, the upper portion of the till typically has a very stiff to hard consistency within 3 m of ground surface and the till becomes stiff to very stiff with localized firm zones at greater depths.

July 27, 2018

Laboratory testing conducted on samples of the till measured natural moisture contents of between approximately 6 % and 18 %.

Grain size distribution tests were completed on four (4) samples of the glacial till. The results of the tests are included in Appendix D and summarized in Table 4.1.

Borehole	Sample	Depth (m)	Unified Soil Classification System	% Gravel	% Sand	% Silt	% Clay
BH18-1	SS6	4.1	SANDY CLAY (CL)	8	28	54	10
BH18-2	SS7	4.9	SANDY SILT (ML)	6	36	53	5
BH18-3B	SS9	6.4	SILTY SAND (SM) with gravel	26	41	25	8
BH18-4	SS3	1.8	SANDY CLAY (CL)	8	41	40	11

Table 4 1.	Grain Size	Distribution	Rosulte -	TILL
1 apre 4.1.	Grain Size	ຬມາວແກນແດດກ	resuits -	

In accordance with the Unified Soil Classification System, the samples tested can be typically be classified as sandy clay (CL) to sandy silt (ML). A sample of the more granular till encountered at a depth of about 6 m in BH18-3B can be classified as silty sand with gravel. It is noted that the gradation results do not represent materials larger than the split spoon diameter. Cobbles and boulders were noted throughout the till deposits.

# 4.6 GROUNDWATER CONDITIONS

Groundwater levels measured within the open boreholes were between 3.8 m and 4.6 m below ground surface upon completion of drilling, corresponding to elevations of 54.8 m to 55.7 m.

A groundwater monitoring well, with a well screen located at a depth of about 4.6 m to 7.6 m below ground surface, was installed in BH18-3B. The groundwater level in this well was recorded to be approximately 4.2 m below ground surface corresponding to an elevation of 55.9 m on July 20, 2018.

Groundwater levels are subject to fluctuations due to seasonal changes and precipitation events. The water levels should be expected to be higher during the spring season or during and following periods of heavy precipitation or snow melt.

# 4.7 CHEMICAL ANALYSIS

Chemical testing related to the potential for corrosivity and sulphate attack was completed on one a selected soil sample from BH18-4. Table 4.2 below summarizes the test results. The laboratory test report is provided in Appendix E.

	<b>a</b> .		Physic	al Characteristic	S	
Borehole No.	Sample No./Depth	% Solids (by Wt.)	рН	Resistivity (Ohm-m)	Chloride (ug/g)	Sulphate (ug/g)
BH18-4	SS3/1.8m	88.7	7.83	34.3	110	31

Table 4.2: Summary of Chemical Testing Results

# 5.0 **DISCUSSION AND RECOMMENDATIONS**

This section provides engineering input related to the geotechnical design aspects of the proposed development based on our interpretation of the available subsurface information described herein and our understanding of the project requirements.

The discussion and recommendations presented in the following sections of this report are intended to provide the designers with preliminary information for planning and design purposes only. Contractors bidding on or undertaking the works should examine the factual results of the investigation, satisfy themselves as to the adequacy of the factual information for construction, and make their own interpretation of the factual data as it affects their proposed construction techniques, schedule, safety, and equipment capabilities.

# 5.1 SEISMIC DESIGN CONSIDERATIONS

### 5.1.1 Seismic Site Class

The seismic Site Class value, as defined in Section 4.1.8.4 of the 2012 Ontario Building Code (OBC), contains a seismic analysis and design methodology which uses a seismic site response and site classification system defined by the average shear stiffness of the upper 30 metres of the ground below the foundation level. There are six site classes (from A to F), decreasing in stiffness from A (hard rock) to E (soft soil); Site Class F denotes problematic soils for which a site-specific evaluation is required.

Based on the results of the current field investigation, it is appropriate to classify the existing ground conditions at the subject site as a Site Class C.

A copy of the NBC Seismic Hazard Calculation Data sheet is provided in Appendix F for reference.

### 5.1.2 Liquefaction Potential

The glacial till deposits that overlie the bedrock at this site consist predominantly of stiff to very stiff clayey soils that are not considered to be susceptible to liquefaction.

# 5.2 FROST PENETRATION

The design frost penetration depth for the Ottawa area is 1.8 m. All foundations founded on frost-susceptible materials should be provided with a minimum of 1.8 metres of earth cover or equivalent insulation for frost protection purposes.

It is to be noted that the above frost penetration depth is applicable only to foundation design. Short period deeper frost penetrations, which would have little impacts on foundations, may occur. The typical soil cover for frost protection of watermains and services is 2.4 m below ground surface in the City of Ottawa.

Exterior slabs-on-grade or slabs-on-grade within unheated areas will also be subject to the risk of heave and deformation/cracking due to frost. Consideration could be given to the use rigid insulation to protect structures against frost action; however appropriate frost tapers would need to be incorporated at the ends of the insulation.

## 5.3 SITE PREPARATION

## 5.3.1 Grade Raise Restrictions

The final site grades in the area of the proposed building are understood to be approximately 59.8 m. The native subsurface materials present at the site consist predominantly of stiff to very stiff, sandy clay till overlying shale bedrock. These materials are not considered to be highly compressible when subjected to light to moderate loads. Therefore, grade raises of less than 1 m, if required, are not anticipated to result in settlements of the underlying soil/bedrock that would adversely affect the performance of the proposed development.

## 5.3.2 Site Preparation and Floor Slab Construction

In preparation for construction of the building foundations and floor slab, all vegetation and tree stumps/roots, organic soil (including topsoil), existing fill materials, existing infrastructure (e.g. foundations, floor slabs and services for the existing buildings) and any loose, wet, and/or otherwise disturbed native material should be removed from within the footprint of the proposed building and any other settlement sensitive areas. To provide consistent subgrade conditions, all below-grade portions of the existing buildings as well as basement wall backfill materials should be removed to expose the native glacial till.

Following removal of the above noted materials, the prepared subgrade will require inspection by geotechnical personnel to verify all unsuitable material has been removed.

The existing basements and foundations of the existing structures at the site are anticipated to extend below the basement floor slab level for the proposed building. Where removal of existing structures and/or unsuitable materials extends below the floor slab subgrade level, the grade beneath the new building floor slab should be raised/reinstated to the design subgrade level using Structural Fill consisting of Ontario Provincial Standard Specification (OPSS) Granular B Type I or II materials that are placed in lifts no thicker than 300 mm and compacted to at least 100% of the material's Standard Proctor Maximum Dry Density (SPMDD).

The floor slab for the lowest level of the proposed building is understood to be located below the final exterior grades. This level should either be designed to be waterproof/watertight or an underslab drainage system should be provided to prevent hydrostatic pressure build-up beneath the floor due to fluctuations in the water table and/or infiltration of surface water. At least 300 mm of free draining material, such as 16 mm clear crushed stone, should be provided beneath the base of the slab. These materials should be lightly-compacted to provide a level surface and improve trafficability during construction. Subdrains consisting of geotextile encapsulated, 100 mm diameter perforated pipes should be provided at approximately 6 m spacings within the floor slab bedding and should be connected to a frost-free gravity outlet or a sump from which the water is pumped. The requirements for a underslab vapour barrier should be determined in accordance with the requirements of the Ontario Building Code.

If existing fill materials or structures are present beneath the proposed founding elevations, all such fill materials and structures should be removed from beneath the footprint of the building, the footings and the zone of influence of all footings, to expose the native glacial till surface. The zone of influence is defined by a line drawn at 1 horizontal to 1 vertical, outward and downward from the edge of the footings. The grade should be raised back up to the founding level using Structural Fill as discussed above. Inspection and testing services will be critical to ensure that all fill, existing structures and unsuitable materials are removed beneath the proposed building, and that new engineered fill and concrete used is suitable and is placed competently.

# 5.4 FOUNDATION DESIGN INPUT

Based on the subsurface conditions encountered at the site and the proposed finished floor slab level of the proposed building, the preferred foundation option for this site is the use of shallow strip and/or spread footings bearing on either the undisturbed native till deposits or compacted Structural Fill placed above the undisturbed till.

## 5.4.1 Foundation Design Parameters - Shallow Footings

Shallow foundations bearing directly on undisturbed native till or on Structural Fill placed above the native till can be designed using factored geotechnical resistance values presented in Table 5.1 below.

Footing Type and Width (m)	Minimum Footing Embedment (m) Below Basement Floor Slab Surface	Factored Geotechnical Resistance at ULS (kPa)	Geotechnical Resistance at SLS (kPa)
Square Footings			
1			200
2	0.8	275	180
2.5			150
Strip Footings			
0.5 to 1.5	0.8	200	150

Table 5.1: Geotechnical Resistance for Shallow Footings

Notes:

The geotechnical resistances in the above table are provided for the range of footing widths and the minimum footing embedment depths (below the basement floor slab surface) listed in the above table.

Additional input should be provided by the geotechnical engineer if the foundation sizes or embedment depths are outside of the ranges outlined above.

The factored geotechnical bearing resistances at ULS incorporate resistance factors of 0.5. The post-construction total and differential settlements of footings sized using the above SLS bearing pressure should be less than about 25 and 20 millimetres, respectively, provided that the soil at or below founding level is not disturbed during construction.

The native soils are highly susceptible to disturbance by construction activity especially during wet or freezing weather. Care should be taken to preserve the integrity of the materials as bearing strata. It is essential that the founding level for the footings be inspected by the geotechnical engineer prior to placing concrete. If the concrete for the footings on the native soil cannot be placed immediately after excavation and inspection, it is recommended that a working mat of lean concrete be placed in the excavation to protect the integrity of the bearing stratum.

The unfactored horizontal resistance to sliding of the spread foundations may be calculated using the following unfactored coefficients of friction:

- 0.55 between OPSS Granular A or B Type II materials and cast-in-place concrete
- 0.4 between sandy clay till and cast-in-place concrete

In accordance with Table 8.1 of the Canadian Foundation Engineering Manual 4<sup>th</sup> Edition (CFEM), a resistance factor ( $\phi$ ) against sliding (for frictional materials) of 0.8 should be applied to obtain the factored resistance at ULS.

### 5.4.2 Foundation Wall Backfill

The soils/fill materials encountered at the site are susceptible to frost heave and should not be used as backfill against exterior, unheated, or well insulated foundation elements within the depth of frost penetration. To avoid problems with frost adhesion and heaving, foundation walls in these areas should be backfilled with non-frost susceptible granular fill meeting the gradation requirements of OPSS Granular B Type I materials. The fill should be placed in maximum 300-millimetre thick lifts and should be compacted to at least 95 percent of the material's SPMDD using suitable vibratory compaction equipment.

In areas where hard surfacing (e.g., concrete slabs, sidewalks) surround the building, differential frost heaving will occur between the granular fill backfill zone and other areas. To reduce this differential heaving, a frost taper of the granular backfill is recommended. The frost taper should extend up from 1.5 metres below finished exterior grade (at the foundation wall) at a slope of 3 horizontal to 1 vertical, or flatter, to the surface level.

Exterior grades should be sloped away from the building to prevent ponding of water around the buildings. As the lowest floor slab level is understood to be below the final exterior grades, the basement wall backfill should be drained using a perimeter drainage system (e.g. perforated subdrain) which is provided positive drainage to storm sewer or to a sump from which water is pumped similar to the underslab drainage system discussed in Section 5.3.2.

## 5.5 EARTH PRESSURES

Earth pressures will need to be considered in the design of the basement walls. The total active ( $P_A$ ), passive ( $P_P$ ) and at-rest ( $P_O$ ) thrusts can be calculated using the following equations:

$$P_{A} = \frac{1}{2} K_{a} \gamma H^{2}$$
$$P_{P} = \frac{1}{2} K_{p} \gamma H^{2}$$
$$P_{O} = \frac{1}{2} K_{o} \gamma H^{2}$$

where;

H = height of the wall  $\gamma$  = unit weight of the backfill soil

Values for  $K_a$ ,  $K_p$ ,  $K_o$  and  $\gamma$  are provided in the table below. These values are based on the assumption that a horizontal back slope is present behind and adjacent to the wall system. The earth pressure coefficients need to be adjusted (i.e. increased) where sloping backfill will be present behind the walls. At-rest earth pressures should be used in the design of walls that are restrained from movement. The thrust acts at a point one third up the height of the wall.

### Table 5.2: Non-Seismic Lateral Earth Pressure Parameters (Horizontal Backfill)

Parameter	OPSS Granular B - Type I
Bulk Unit Weight, γ (kN/m <sup>3</sup> )	22
Effective Friction Angle	32°
Coefficient of Earth Pressure at Rest (K₀)	0.47
Coefficient of Active Earth Pressure (Ka)	0.31
Coefficient of Passive Earth Pressure (Kp)	3.25

Total active and passive thrusts under earthquake conditions can be calculated using the following equations:

 $P_{AE} = \frac{1}{2} K_{AE} \gamma H^2$  $P_{PE} = \frac{1}{2} K_{PE} \gamma H^2$ 

where;

K<sub>AE</sub> = active earth pressure coefficient (combined static and seismic) K<sub>PE</sub> = passive earth pressure coefficient (combined static and seismic) H = height of wall  $\gamma$  = total unit weight

The recommended seismic earth pressure parameters are provided in Table 4.3 below. The angle of friction between the soil and the wall has been assumed to be 0° to provide a conservative estimate.

Table 5.3:	Seismic Earth Pressure Parameters (Horizontal Backf	ill)

Parameter	OPSS Granular B - Type I
Bulk Unit Weight, γ (kN/m <sup>3</sup> )	22
Effective Friction Angle	32°
K <sub>AE</sub> (Non-Yielding Wall)	0.51
Height of Application of $P_{AE}$ from base as a ratio of wall height, (H) – Non Yielding Wall	0.44
Active Earth Pressure (KAE) – Yielding Wall	0.4
Height of Application of PAE from base as a ratio of wall height, (H) - Yielding Wall	0.39
Passive Earth Pressure, (K <sub>PE</sub> )	2.99
Height of Application of $P_{PE}$ from base as a ratio of wall height, (H)	0.31

In order to use the coefficients of pressure for the granular materials presented in the tables above, the granular backfill must be provided within a wedge extending out from the base of the wall at 45 degrees (or smaller) to the horizontal.

#### **EXCAVATIONS AND BACKFILL** 5.6

### 5.6.1 Temporary Excavations

All temporary excavations should be carried out in accordance with the Occupational Health and Safety Act and Regulations for Construction Projects. Care should be taken to direct surface water away from the open excavations.

July 27, 2018

The excavation side slopes should be protected from precipitation or surface runoff to prevent further softening that could lead to additional sloughing and caving. If sloughing and/or cave-ins are encountered in the excavation, the slopes should be further flattened to achieve a stable configuration.

Excavations required for the building construction are expected to typically be less than 2 m in depth although localized, deeper excavations could be required (e.g. for service connection tie-ins).

Shallow excavations within the overburden at the site are anticipated to extend through fill materials and the native glacial till deposit. Conventional hydraulic excavating equipment is considered suitable for developing excavations in these materials. recognizing that additional effort will be required to remove cobbles and boulders within the glacial till. Boulders larger than 0.3 metres in size should be removed from the excavation side slopes.

The existing fill materials and the native glacial till deposit that are above the water table would be classified as Type 3 soils as defined by Occupational Health and Safety Act (OHSA) and Regulations for Construction Projects. Within Type 3 soils, temporary open cut excavations must be sloped at 1 horizontal to 1 vertical from the base of the excavation per the requirements of OHSA.

The excavation sideslopes would need to be flattened and/or appropriate groundwater control measures implemented if excavations are carried out in overburden materials below the water table.

The excavations must be developed in a manner to ensure that adequate support is provided for any existing structures, utilities or underground services located adjacent to the excavations. Where there is insufficient space to develop open cuts without resultant loss of support for existing features or encroaching into adjacent properties, the installation of a shoring system meeting the requirements of the OHSA would be required. All shoring systems should be designed and approved by a qualified Professional Engineer. The excavation support system should be designed to resist loads from traffic and adjacent building foundations.

### 5.6.2 Temporary Dewatering Considerations

The groundwater level measured in the piezometer installed in Borehole BH18-03B was measured to be at a depth of about 4.2 m below ground surface.

Control of groundwater into shallow excavations into the glacial till is expected to be able to be handled by filtered sumps within the excavation areas. More significant groundwater inflows should be expected for deeper excavations that extend below the ground water level and penetrate the more granular zones within the till.. More extensive dewatering systems (e.g. external dewatering system using well points or other dewatering wells) could be required for such conditions. Depending on the depth of excavations, dewatering activities may require either registration in the Ministry of the Environment and Climate Change (MOECC) Environmental Activity and Sector Registry (EASR) or obtaining a Permit to Take Water (PTTW) from the MOECC depending on the anticipated groundwater removal rates. If deep excavations extending below the water table are required, a separate hydrogeological assessment, should be completed to confirm these requirements before such excavations are undertaken. This assessment should include measurement of the in situ hydraulic conductivity of the site soils.

# 5.7 PIPE BEDDING AND BACKFILL

OPSS Granular A materials should be placed below sewer and water pipes as bedding material. The bedding should have a minimum thickness of 150 mm to meet City of Ottawa standards. Where unavoidable disturbance to the subgrade surface does occur, it may be necessary to thicken the bedding layer or provide a sub-bedding layer of compacted Granular B Type II materials. Pipe backfill and cover materials should also consist of OPSS Granular A material. A minimum thickness of 300 mm of these materials should be provided as vertical and side cover beside and over top of the pipes. These materials should be compacted to at least 95% of the material's SPMDD in lifts no greater than 300 mm. Clear crushed stone backfill should not be permitted as pipe bedding or cover materials.

Where the pipe trenches will be covered with hard surfaced areas, the type of native material placed in the frost zone (i.e. between subgrade level and the top of the pipe cover materials) should match the soil exposed on the trench walls for frost heave compatibility. A 3H:1V frost taper is recommended in order to minimize the effects of differential frost heaving if materials different than those present in excavation sidewalls are used as backfill.

Trench backfill above the pipe cover materials should be placed in maximum 300 mm thick lifts and should be compacted to at least 98 % of the material's SPMDD using suitable vibratory compaction equipment.

The existing fill materials and the native glacial till that are free of organic matter and other deleterious materials, may be considered suitable for reuse as trench backfill or as general site grade fill (i.e. materials used to raise the site grade to the design elevations). The ability to compact these materials to the required levels is dependent on the moisture content of the materials; thus, the amount of re-useable material will be dependent on the natural moisture content, weather conditions and the construction techniques at the time of excavation and placement. In addition, any boulders or cobbles with dimensions greater than 150 mm should be removed from these materials prior to placement.

Any imported fill materials proposed for use as bedding or trench backfill should be tested and approved by a geotechnical engineering firm prior to delivery to the site.

Materials testing and inspection should be carried out during construction to ensure the materials meet the project specifications and required level of compaction.

# 5.8 ADVERSE WEATHER CONSTRUCTION

Additional precautions, effort, and measures may be required, when and where construction is undertaken during late fall, winter, and/or early spring (i.e. when the temperature and climatic conditions can have an adverse influence on the standard construction practices) or during periods of inclement weather. With respect to all earthworks activities undertaken during the late fall through to late spring, when less-than-ideal weather and construction conditions may prevail, the following comments are provided:

- 1. Foundations shall be constructed on non-frozen ground only; where non-frozen ground includes the material at surface and all underlying soils. The non-frozen nature of the ground must be confirmed by a geotechnical inspection within 1 hour of concrete placement.
- 2. Similarly, concrete for floor slabs should not be placed or above frozen ground. Test pits or other measures should be undertaken to confirm that the soils beneath the slab(s) are frost-free prior to slab construction.

- 3. Following construction of footings, protection measures must be provided to prevent freezing of the foundation subgrade/bearing soils and for protection of the concrete during curing.
- 4. Engineered fills including pipe bedding and cover, are recommended to consist of imported granular materials, including OPSS Granular A or B materials. The use of non-granular fill materials may be considered for use as trench backfill but obtaining suitable compaction of such materials could be extremely problematic, and these materials should only be used if large, post-construction settlement of the trench backfill is deemed acceptable.
- 5. Fill placement should be inspected by qualified field personnel on a <u>full-time basis</u> under the supervision of a geotechnical engineer, with the authority to stop the placement of fill at any time when conditions are considered to be unfavourable.
- 6. Backfill materials, including imported materials, that contain ice, snow, or any frozen material should not be accepted for use.
- 7. Overnight frost penetration may occur, even in granular fill materials, where precipitation and ground surface runoff pools and accumulates, and freezing temperatures exist. The on-site clayey soils are prone to frost heave due to ice lensing. Any frozen materials should be removed prior to placing subsequent lifts of engineered fill. Breaking the frost in-situ is not considered acceptable.
- 8. It may be necessary to stop the placement of engineered fill during periods of cold, where ambient temperatures are -5° C or less exist.

Appropriate scheduling of the work may also require specific consideration and revision from that typically adopted. The scope of work intended may have to be reduced or adjusted, and/or only select construction activities be undertaken during specific climatic conditions. The areas of planned fill placement may have to be reduced on a daily basis, and the extent of excavations may have to be limited.

# 5.9 CEMENT TYPE AND CORROSION POTENTIAL

One (1) test was conducted on a selected soil sample to determine the water soluble sulphate content of the site soils. The sulphate concentration in the sample was 31 ug/g as shown in Table 4.2.

The concentration of soluble sulphate provides an indication of the degree of sulphate attack that is expected for concrete in contact with soil and groundwater at the site. Soluble sulphate concentrations less than 1000  $\mu$ g/g generally indicate that a low degree of sulphate attack is expected for concrete in contact with the soil and groundwater. General Use (GU) Portland cement is appropriate for use at the site.

The test results provided in Table 4.2 should be used by the designers in assessing the potential for corrosion of steel elements and may be used to aid in the selection of coatings and corrosion protection systems for buried steel objects. The soil pH result of 7.83 is within what is considered the normal range for soil pH of 5.5 to 9.0. The pH level of the tested soil does not indicate a highly corrosive environment. The reported resistivity of 34.3 (ohm-m) suggests a moderate degree of corrosiveness for steel.

# 6.0 CLOSURE

Not all details related to the proposed development are known at this time. In this regard, all geotechnical comments provided in this report should be reviewed and, if necessary, revised once the final plans become available. Stantec should be retained to review the final drawings and specifications to confirm that the geotechnical input provided herein has been adequately addressed.

This report has been prepared for the sole benefit of TC United Group and their agents, and may not be used by any third party without the express written consent of Stantec Consulting Ltd. and TC United Group. Any use, which a third party makes of this report, is the responsibility of such third party. Use of this report is subject to the Statement of General Conditions provided in Appendix A. It is the responsibility of TC United Group, who is identified as "the Client" within the Statement of General Conditions, and its agents to review the conditions and to notify Stantec Consulting Ltd. should any of these not be satisfied. The Statement of General Conditions addresses the following:

- Use of the report
- Basis of the report
- Standard of care
- Interpretation of site conditions
- Varying or unexpected site conditions
- Planning, design or construction

We trust the above information meets with your present requirements. Should you have any questions or require further information, please contact us. This report has been prepared by Ramy Saadeldin, Ph.D., P.Eng. and reviewed by Kevin Nelson, P.Eng.

Thank you for the opportunity to be of service to you.

Respectfully submitted,

### STANTEC CONSULTING LTD.

Ramy Saadeldin, PhD, P.Eng. Senior Geotechnical Engineer

Kevin Nelson, P.Eng. Principal, Geotechnical Engineering

Statement of General Conditions

### STATEMENT OF GENERAL CONDITIONS

<u>USE OF THIS REPORT</u>: This report has been prepared for the sole benefit of the Client or its agent and may not be used by any third party without the express written consent of Stantec Consulting Ltd. and the Client. Any use which a third party makes of this report is the responsibility of such third party.

<u>BASIS OF THE REPORT</u>: The information, opinions, and/or recommendations made in this report are in accordance with Stantec Consulting Ltd.'s present understanding of the site specific project as described by the Client. The applicability of these is restricted to the site conditions encountered at the time of the investigation or study. If the proposed site specific project differs or is modified from what is described in this report or if the site conditions are altered, this report is no longer valid unless Stantec Consulting Ltd. is requested by the Client to review and revise the report to reflect the differing or modified project specifics and/or the altered site conditions.

<u>STANDARD OF CARE</u>: Preparation of this report, and all associated work, was carried out in accordance with the normally accepted standard of care in the state or province of execution for the specific professional service provided to the Client. No other warranty is made.

<u>INTERPRETATION OF SITE CONDITIONS</u>: Soil, rock, or other material descriptions, and statements regarding their condition, made in this report are based on site conditions encountered by Stantec Consulting Ltd. at the time of the work and at the specific testing and/or sampling locations. Classifications and statements of condition have been made in accordance with normally accepted practices which are judgmental in nature; no specific description should be considered exact, but rather reflective of the anticipated material behavior. Extrapolation of in situ conditions can only be made to some limited extent beyond the sampling or test points. The extent depends on variability of the soil, rock and groundwater conditions as influenced by geological processes, construction activity, and site use.

<u>VARYING OR UNEXPECTED CONDITIONS</u>: Should any site or subsurface conditions be encountered that are different from those described in this report or encountered at the test locations, Stantec Consulting Ltd. must be notified immediately to assess if the varying or unexpected conditions are substantial and if reassessments of the report conclusions or recommendations are required. Stantec Consulting Ltd. will not be responsible to any party for damages incurred as a result of failing to notify Stantec Consulting Ltd. that differing site or subsurface conditions are present upon becoming aware of such conditions.

<u>PLANNING, DESIGN, OR CONSTRUCTION</u>: Development or design plans and specifications should be reviewed by Stantec Consulting Ltd., sufficiently ahead of initiating the next project stage (property acquisition, tender, construction, etc), to confirm that this report completely addresses the elaborated project specifics and that the contents of this report have been properly interpreted. Specialty quality assurance services (field observations and testing) during construction are a necessary part of the evaluation of sub-subsurface conditions and site preparation works. Site work relating to the recommendations included in this report should only be carried out in the presence of a qualified geotechnical engineer; Stantec Consulting Ltd. cannot be responsible for site work carried out without being present.

# **APPENDIX B**

Drawing No. 1 – Borehole Location Plan

2. BASEPLAN PROVIDED BY TC UNITED GROUP (FILENAME: 1821 X - SitePlan.dwg)

# **APPENDIX C**

Symbols & Terms Used on the Borehole Records Borehole Records

### SYMBOLS AND TERMS USED ON BOREHOLE AND TEST PIT RECORDS

### SOIL DESCRIPTION

### Terminology describing common soil genesis:

Rootmat	<ul> <li>vegetation, roots and moss with organic matter and topsoil typically forming a mattress at the ground surface</li> </ul>
Topsoil	- mixture of soil and humus capable of supporting vegetative growth
Peat	- mixture of visible and invisible fragments of decayed organic matter
Till	- unstratified glacial deposit which may range from clay to boulders
Fill	- material below the surface identified as placed by humans (excluding buried services)

### Terminology describing soil structure:

Desiccated	- having visible signs of weathering by oxidization of clay minerals, shrinkage cracks, etc.
Fissured	- having cracks, and hence a blocky structure
Varved	- composed of regular alternating layers of silt and clay
Stratified	- composed of alternating successions of different soil types, e.g. silt and sand
Layer	- > 75 mm in thickness
Seam	- 2 mm to 75 mm in thickness
Parting	- < 2 mm in thickness

### Terminology describing soil types:

The classification of soil types are made on the basis of grain size and plasticity in accordance with the Unified Soil Classification System (USCS) (ASTM D 2487 or D 2488) which excludes particles larger than 75 mm. For particles larger than 75 mm, and for defining percent clay fraction in hydrometer results, definitions proposed by Canadian Foundation Engineering Manual, 4<sup>th</sup> Edition are used. The USCS provides a group symbol (e.g. SM) and group name (e.g. silty sand) for identification.

### Terminology describing cobbles, boulders, and non-matrix materials (organic matter or debris):

Terminology describing materials outside the USCS, (e.g. particles larger than 75 mm, visible organic matter, and construction debris) is based upon the proportion of these materials present:

Trace, or occasional	Less than 10%
Some	10-20%
Frequent	> 20%

### Terminology describing compactness of cohesionless soils:

The standard terminology to describe cohesionless soils includes compactness (formerly "relative density"), as determined by the Standard Penetration Test (SPT) N-Value - also known as N-Index. The SPT N-Value is described further on page 3. A relationship between compactness condition and N-Value is shown in the following table.

Compactness Condition	SPT N-Value
Very Loose	<4
Loose	4-10
Compact	10-30
Dense	30-50
Very Dense	>50

### Terminology describing consistency of cohesive soils:

The standard terminology to describe cohesive soils includes the consistency, which is based on undrained shear strength as measured by *in situ* vane tests, penetrometer tests, or unconfined compression tests. Consistency may be crudely estimated from SPT N-Value based on the correlation shown in the following table (Terzaghi and Peck, 1967). The correlation to SPT N-Value is used with caution as it is only very approximate.

Consistency	Undrained Sh	Approximate	
Consistency	kips/sq.ft.	kPa	SPT N-Value
Very Soft	<0.25	<12.5	<2
Soft	0.25 - 0.5	12.5 - 25	2-4
Firm	0.5 - 1.0	25 - 50	4-8
Stiff	1.0 - 2.0	50 – 100	8-15
Very Stiff	2.0 - 4.0	100 - 200	15-30
Hard	>4.0	>200	>30

### ROCK DESCRIPTION

Except where specified below, terminology for describing rock is as defined by the International Society for Rock Mechanics (ISRM) 2007 publication "The Complete ISRM Suggested Methods for Rock Characterization, Testing and Monitoring: 1974-2006"

### Terminology describing rock quality:

RQD	Rock Mass Quality		Alternate (Colloquio	al) Rock Mass Quality
0-25	Very Poor Quality		Very Severely Fractured	Crushed
25-50	Poor Quality		Severely Fractured	Shattered or Very Blocky
50-75	Fair Quality		Fractured	Blocky
75-90	Good Quality		Moderately Jointed	Sound
90-100	Excellent Quality		Intact	Very Sound

**RQD (Rock Quality Designation)** denotes the percentage of intact and sound rock retrieved from a borehole of any orientation. All pieces of intact and sound rock core equal to or greater than 100 mm (4 in.) long are summed and divided by the total length of the core run. RQD is determined in accordance with ASTM D6032.

**SCR (Solid Core Recovery)** denotes the percentage of solid core (cylindrical) retrieved from a borehole of any orientation. All pieces of solid (cylindrical) core are summed and divided by the total length of the core run (It excludes all portions of core pieces that are not fully cylindrical as well as crushed or rubble zones).

**Fracture Index (FI)** is defined as the number of naturally occurring fractures within a given length of core. The Fracture Index is reported as a simple count of natural occurring fractures.

### Terminology describing rock with respect to discontinuity and bedding spacing:

Spacing (mm)	Discontinuities	Bedding
>6000	Extremely Wide	-
2000-6000	Very Wide	Very Thick
600-2000	Wide	Thick
200-600	Moderate	Medium
60-200	Close	Thin
20-60	Very Close	Very Thin
<20	Extremely Close	Laminated
<6	-	Thinly Laminated

### Terminology describing rock strength:

Strength Classification	Grade	Unconfined Compressive Strength (MPa)
Extremely Weak	RO	<1
Very Weak	R1	1 – 5
Weak	R2	5 – 25
Medium Strong	R3	25 – 50
Strong	R4	50 – 100
Very Strong	R5	100 – 250
Extremely Strong	R6	>250

### Terminology describing rock weathering:

Term	Symbol	Description
Fresh	W1	No visible signs of rock weathering. Slight discoloration along major discontinuities
Slightly	W2	Discoloration indicates weathering of rock on discontinuity surfaces. All the rock material may be discolored.
Moderately	W3	Less than half the rock is decomposed and/or disintegrated into soil.
Highly	W4	More than half the rock is decomposed and/or disintegrated into soil.
Completely	W5	All the rock material is decomposed and/or disintegrated into soil. The original mass structure is still largely intact.
Residual Soil	W6	All the rock converted to soil. Structure and fabric destroyed.

### RECOVERY

PS

BS

HQ, NQ, BQ, etc.

For soil samples, the recovery is recorded as the length of the soil sample recovered. For rock core, recovery is defined as the total cumulative length of all core recovered in the core barrel divided by the length drilled and is recorded as a percentage on a per run basis.

### N-VALUE

Numbers in this column are the field results of the Standard Penetration Test: the number of blows of a 140 pound (63.5 kg) hammer falling 30 inches (760 mm), required to drive a 2 inch (50.8 mm) O.D. split spoon sampler one foot (300 mm) into the soil. In accordance with ASTM D1586, the N-Value equals the sum of the number of blows (N) required to drive the sampler over the interval of 6 to 18 in. (150 to 450 mm). However, when a 24 in. (610 mm) sampler is used, the number of blows (N) required to drive the sampler over the interval of 6 to 18 in. (150 to 450 mm). However, when a 24 in. (610 mm) may be reported if this value is lower. For split spoon samples where insufficient penetration was achieved and N-Values cannot be presented, the number of blows are reported over sampler penetration in millimetres (e.g. 50/75). Some design methods make use of N-values corrected for various factors such as overburden pressure, energy ratio, borehole diameter, etc. No corrections have been applied to the N-values presented on the log.

### DYNAMIC CONE PENETRATION TEST (DCPT)

Piston sample

Rock core samples obtained with the use

of standard size diamond coring bits.

Bulk sample

Dynamic cone penetration tests are performed using a standard 60 degree apex cone connected to 'A' size drill rods with the same standard fall height and weight as the Standard Penetration Test. The DCPT value is the number of blows of the hammer required to drive the cone one foot (300 mm) into the soil. The DCPT is used as a probe to assess soil variability.

### OTHER TESTS

Stantec

S	Sieve analysis
Н	Hydrometer analysis
k	Laboratory permeability
Ŷ	Unit weight
Gs	Specific gravity of soil particles
CD	Consolidated drained triaxial
CU	Consolidated undrained triaxial with pore
	pressure measurements
UU	Unconsolidated undrained triaxial
DS	Direct Shear
С	Consolidation
Qu	Unconfined compression
	Point Load Index (Ip on Borehole Record equals
Ιp	$I_p$ (50) in which the index is corrected to a
	reference diameter of 50 mm)

Ţ	Single packer permeability test; test interval from depth shown to bottom of borehole
	Double packer permeability test; test interval as indicated
Î	Falling head permeability test using casing
Ţ	Falling head permeability test using well point or piezometer

### **Qualifier Notes:**

Login Qualifiers :

Received at temperature > 25C Applies to samples: 121622041, 18-4, SS-3, 5'-7'

Sample Data Revisions

None

Work Order Revisions / Comments:

None

#### **Other Report Notes:**

n/a: not applicable ND: Not Detected MDL: Method Detection Limit Source Result: Data used as source for matrix and duplicate samples %REC: Percent recovery. RPD: Relative percent difference.

Soil results are reported on a dry weight basis when the units are denoted with 'dry'. Where %Solids is reported, moisture loss includes the loss of volatile hydrocarbons.

# **APPENDIX F**

Seismic Hazard Calculation Sheet

# 2015 National Building Code Seismic Hazard Calculation

INFORMATION: Eastern Canada English (613) 995-5548 français (613) 995-0600 Facsimile (613) 992-8836 Western Canada English (250) 363-6500 Facsimile (250) 363-6565

Site: 45.4185 N, 75.666 W User File Reference: 27 Robinson Avenue, Ottawa, ON Requested by: RS, Stantec Consulting Ltd.

### National Building Code ground motions: 2% probability of exceedance in 50 years (0.000404 per annum)

Sa(0.05)	Sa(0.1)	Sa(0.2)	Sa(0.3)	Sa(0.5)	Sa(1.0)	Sa(2.0)	Sa(5.0)	Sa(10.0)	PGA (g)	PGV (m/s)
0.450	0.526	0.441	0.335	0.238	0.118	0.056	0.015	0.0054	0.282	0.197

**Notes.** Spectral (Sa(T), where T is the period in seconds) and peak ground acceleration (PGA) values are given in units of g (9.81 m/s<sup>2</sup>). Peak ground velocity is given in m/s. Values are for "firm ground" (NBCC 2015 Site Class C, average shear wave velocity 450 m/s). NBCC2015 and CSAS6-14 values are specified in **bold** font. Three additional periods are provided - their use is discussed in the NBCC2015 Commentary. Only 2 significant figures are to be used. *These values have been interpolated from a 10-km-spaced grid of points. Depending on the gradient of the nearby points, values at this location calculated directly from the hazard program may vary. More than 95 percent of interpolated values are within 2 percent of the directly calculated values.*
