1.0 INTRODUCTION

Introduction

Paterson Group (Paterson) was commissioned by TC United Development on behalf of Robinson Village LPIV Limited Partnership to prepare a hydrogeological review for the proposed multi-storey building to be located at 36 Robinson Avenue in Ottawa, Ontario (refer to Figure 1.2 - Site Plan by others within Appendix 1).

Subsurface information was obtained from the field investigations carried out by Paterson and others to determine the subsoil and groundwater conditions at the site by means of test holes.

The following report has been prepared specifically and solely for the aforementioned project which is described herein. It contains the investigation findings and includes hydrogeological assessments pertaining to the proposed program as understood at the time of writing this report.

Proposed Project

It is our understanding that the proposed development will consist of a multi-storey building with three levels of underground parking. The P-3 level floor slab has been proposed at an elevation of 50.2 m. It is further understood that the proposed parking structure will occupy the entire subject site and the site will be municipally serviced.

The proposed development will incorporate a water suppression system that will reduce infiltration volumes and long term groundwater lowering at the post-construction stage. The water suppression system will consist of a horizontal concrete hydraulic barrier at the base of the excavation and a waterproofing membrane along the vertical surfaces. Any groundwater breaching the waterproofing system will be managed by the building sump pit system. Further details regarding the water suppression system have been included in geotechnical Paterson Report PG5231-1 - Revision 2 dated May 12, 2020.

2.0 SITE CONDITIONS

2.1 Surface Conditions

The subject site consists of 5 contiguous properties identified as 36 Robinson Avenue and is currently occupied by residential dwellings that will be demolished prior to redevelopment. The topography of the site is relatively flat and at grade with the surrounding roadways, with an approximate 1 m elevation difference sloping downwards towards the northeast. It is bordered to the northwest by Robinson Avenue, to the northeast and southeast by townhouse style residential dwellings followed by Robinson Avenue, and to the southwest by single residential dwellings.

According to available mapping, the subject site is located in the Ottawa Valley Clay Plains physiographic region.

Field Investigations

A geotechnical field investigation completed by Paterson was carried out on February 21, 2020. At that time, a total of 6 test pits were excavated to a maximum depth of 6.2 m below ground surface (bgs). Previous subsoil and hydrogeological investigations completed by others in 2019 have also been included as part of the current hydrogeological review. The previous investigations consisted of 12 boreholes extending to a maximum depth of 16.6 m bgs. The test hole locations were distributed in a manner to provide general coverage of the subject site taking into consideration site features as well as evaluate any environmental concerns. The borehole locations of the field investigations are presented on Drawing PG5231-1 and Figure 3.1 by others, included in Appendix 2.

The subsurface conditions observed in the test holes were recorded in detail in the field. The soil profiles are presented on the Borehole Log Records by others and the Soil Profile and Test Data sheets in Appendix 2 of this report.

Surface Water

The subject site is located within the Rideau River-Falls subwatershed. The only surface water feature identified within 500 m of the subject site is the Rideau River. Given the meandering nature of the watercourse, the Rideau River is located approximately 80 m to the north, 110 m to the east and 350 m to the south.

Groundwater

Groundwater monitoring wells were installed in select boreholes by others to permit the monitoring of the groundwater levels at the subject site. Observations of groundwater infiltration were also noted in the open hole excavations by Paterson. Groundwater information is discussed in Sections 3 of this report and details are noted on the Borehole Log Records by others and Soil Profile and Test Data sheets presented in Appendix 2 of this report.

2.2 Subsurface Profile

The subsurface profile at the subject site is generally comprised of fill material followed by a sandy silt/silty sand and/or clayey silt layers. The above noted layers are underlain by a glacial till deposit extending to the bedrock surface. Practical refusal to excavation was encountered at select test pit locations between 5.8 and 6.2 m bgs, while bedrock was encountered between 5.3 and 7.8 m bgs.

Reference should be made to the soil profile records and test hole locations completed by Paterson and others included in Appendix 2 for the details of the soil profiles encountered at each borehole location.

Based on surficial mapping prepared by the Ontario Geological Survey, the subject site is located in an area where surficial geology consists of a fluvial deposit comprised of gravel, sand, silt and clay deposited on modern flood plains.

Fill Material

A fill layer was encountered in all test holes at ground surface or underlying the asphaltic concrete. The fill material consisted of varying amounts of silty sand, clay, gravel, organics and construction debris. The fill material extended to a maximum depth of 3.7 m bgs.

Clayey Silt

Generally, the loose to dense clayey silt was encountered beneath the fill material in select boreholes and extended to a maximum depth of 3.8 m bgs.

Silty Sand

A loose to dense grey to brown silty sand layer with some clay and gravel was encountered in all boreholes underlying the fill material and/or clayey silt and extended to a maximum depth of 7.1 m bgs.

Sandy Silt

A very loose to very dense grey sandy silt layer with some clay and trace gravel was encountered in select boreholes underlying the fill material and/or silty sand and extended to a maximum depth of 5.3 m bgs.

Glacial Till

Generally, the compact to very dense glacial till deposit was noted underlying the silty sand and/or sandy silt in select boreholes. The glacial till deposit consists of clayey silt to silty sand matrix with varying amounts gravel with occasional cobbles and boulders and it extends to a maximum depth of 7.8 m bgs.

Bedrock

Based on coring results completed by others, shale bedrock was encountered between 5.3 and 7.8 m bgs and was cored to a maximum depth of 16.6 m bgs. The recovery values ranged from 50 to 100%, while the RQD values generally varied between 0 and 100%. Based on these results the quality of the bedrock ranges from very poor to excellent.

Based on available geological mapping, the subject site is located in an area where the bedrock consists of shale of the Carlsbad Formation with an overburden thickness between 5 and 10 m.

3.0 HYDROGEOLOGY

Subsequent to the subsurface investigations completed at the subject site, groundwater levels were measured at the borehole locations by Paterson and others and ranged from 1 to 4.8 m bgs. However, groundwater levels may have been influenced by surface water infiltrating the backfilled boreholes. Groundwater infiltration was also observed by Paterson during the excavation of the test pits across the subject site and varied between 5.4 and 5.7 m bgs. It should be noted that long-term groundwater levels can also be estimated based on the observed colour and consistency of the recovered soil samples. Based on these observations, a grey silty sand/sandy silt was generally encountered between 3 to 4 m below ground surface and is expected to be the approximate long-term groundwater table. It should also be noted that groundwater levels can fluctuate both seasonally and in conjunction with precipitation events. Therefore, the groundwater levels could vary at the time of construction. Groundwater level measurements have been summarized in Table 1 included in Appendix 3.

On a conceptual scale, hydrogeological/hydrologic conditions at the subject site suggest that water may infiltrate the open excavation as surface water infiltration during precipitation events and through groundwater flow within the overburden and bedrock at depth.

The excavation footprint related to the proposed multi-storey building at the subject site is expected to encompass an area of approximately 1,800 m². Therefore, the potential exists for a low amount of surface water to intercept the excavation footprint directly during significant precipitation events.

In terms of groundwater flow, the building excavation is expected to intercept the silty sand/sandy silt, glacial till and bedrock within the anticipated saturated depth of excavation. The potential exists for a low to moderate amount of groundwater inflow through the overburden and bedrock. The volume of groundwater that infiltrates through the overburden and bedrock will depend on the variability of the soil and the extent of weathering/fracturing in the bedrock across the subject site.

Based on the groundwater levels at the borehole locations, the local groundwater flow direction generally trends in a northerly direction. The regional groundwater flow direction is expected to trend northeast towards the Rideau River and following regional topography. It should be noted that groundwater levels can fluctuate based on precipitation events and seasonal variations. Therefore, groundwater levels and flow directions may vary at the time of construction.

3.1 Estimated Water Taking Rates

The potential sources of water taking at the subject site have been identified as the excavation footprint of the proposed building during the construction phase as well as long-term groundwater infiltration at post-construction.

The hydraulic conductivity values of the silty sand and bedrock were determined based on single well response tests (rising head test) completed by others at the subject site. Based on the testing, the hydraulic conductivity of the silty sand is 1.5×10^{-7} m/sec, while bedrock varied from 5.1×10^{-8} to 1.5×10^{-6} m/sec and is dependant on the quality of the bedrock. Hydraulic conductivity results from the single well response tests completed by others have been included in Appendix 3.

To determine surface water infiltration into the excavation footprint, an intensity duration frequency (IDF) curve from the Ministry of Transportation - Ontario (MTO) was obtained. The IDF curve is the graphical representation of the probability that a given average rainfall intensity will occur. For the purposes of this project, a 5 year storm event with a one hour duration was chosen as the design storm. This provides a potential rainfall intensity of 2.63 x 10^{-2} m of precipitation into the excavation footprint. Various duration storm events with their associated rainfall intensities are presented in the IDF Curve in Appendix 3.

The infiltration rates provided for the following source was calculated using the Dupuit Forchheimer method:

 $Q = \pi K((h_0^2 - h_p^2)/ln(R/r))$

- \Box K = hydraulic conductivity (m/sec)
- \Box h₀ = thickness of the aquifer (m)
- $\square \quad h_p = \text{thickness of the aquifer from the base of the excavation to the base of the aquifer (m)}$
- \Box R = effective drawdown radius for the excavation (m)
- \Box r = equivalent radius of the excavation (m)

A sample groundwater infiltration calculation is provided in Appendix 3 of this report.

Building Excavation Footprint (Construction Dewatering)

The strata at the proposed building location consists of sandy silt/silty sand followed by glacial till and very poor to excellent bedrock within the anticipated saturated depth of excavation. The maximum depth of excavation is expected to be approximately 10 m bgs to accommodate the horizontal concrete hydraulic barrier at the base of the excavation and sump pit system. Calculations are based on an excavation sizing of 1,800 m² and a saturated depth of excavation of 8 m, using a conservative groundwater level measurement of 2 m bgs. Using the above noted values and a conservative hydraulic conductivity of 1.5×10^{-6} m/sec, the steady state volume of groundwater anticipated is approximately **125,000 L/day**, and does not account for the initial groundwater inflow into the excavation or unforseen circumstances.

A factor of safety between 2 and 3 should be applied to the calculated infiltration rates to account for variability in the overburden material, quality of bedrock and any unforseen circumstances that may arise during construction activities.

With respect to the potential for surface water inflow into the excavation footprint, the proposed multi-storey building is adjacent to developed land on all sides. It is therefore expected that the majority of surface water inflow into the excavation footprint will be caused by precipitation directly onto the footprint rather than runoff from other sources. Given an excavation footprint with a sizing of 1,800 m² and a precipitation depth of 2.63 x 10^{-2} m, a total volume of approximately 50,000 L of surface water can be expected during a 5 year - 1 hour duration precipitation event. It is expected that the contractor will direct surface water away from open excavations whenever possible.

Post-Construction (Long-Term Dewatering)

Long-term groundwater infiltration breaching the water suppression system at postconstruction will be managed by the building sump pit system. Provided the proposed groundwater infiltration control system is properly installed and approved by the geotechnical engineer at the time of construction, a conservative 1 m drawdown in the groundwater table at the subject site could be expected. The steady state volume of groundwater anticipated post-construction is approximately **10,000 to 20,000 L/day**.

3.2 Estimated Radius of Influence

A series of calculations were carried out on theoretical radii of influence for the likely duration of extended pumping during the excavation of the building and postconstruction. These calculations were completed based on Sichardt (1992) using the equation: $R = r_e + 3000^* \Delta h(k^{0.5})$

- \Box R = radius of influence (m)
- \Box r_e = equivalent radius of excavation (m)
- \Box Δh = thickness of drawdown within the aquifer (m)
- □ k = hydraulic conductivity (m/sec)

For the purposes of completing the calculations, the following assumptions were made:

- \Box r_e = 28 m (building excavation); 4 m (post-construction)
- \Box k = 1.5 x 10⁻⁶ to 5.1 x 10⁻⁸ m/sec, based upon single well response tests.
- \Box $\Delta h = 7$ to 9 m (building excavation); 0.5 to 1.5 (post-construction), to review potential minimum/maximum variable conditions.

Using the above equation and assumptions, a radius of influence of approximately **5 to 33 m** will develop as a steady state condition, extending from the edge of the excavation, during the construction of the proposed building. It's expected that recharging from precipitation events and with a reasonable foundation construction schedule, **the radius of influence will be approximately 10 to 15 m**.

With the water suppression system in place, it is expected that a radius of influence of approximately **0.5 to 5.5 m** will develop as a steady state condition, extending from the edge of the building, at post-construction.

3.3 Water Discharge

The discharge point for the pumped water from the excavation sump is expected to be to the existing City of Ottawa sewer system via a sewer connection. As such, it will be subject to the City of Ottawa Sewer Use Bylaws and a permit will be required to discharge the water to the sewer system.

It is expected that BMP's as recommended by the City of Ottawa - Sewer Use Program (SUP) document (attached within Appendix 5) or similar will be used to reduce sediment loading within the water prior to discharge to the sewer system. If the pumped water does not meet the SUP criteria, it must be retained on site until test results indicate compliance with the SUP criteria or remove the water through other means such as tanker trucks.

Given the size of the excavation for the proposed development, the volumes of surface water pumped during a 100 year storm event are not expected to exceed the capacity of the nearby City sewer system. Should volumes exceed the available capacity, it's expected that water will be stored on site temporarily and released at an acceptable rate or removed via tanker trucks. The approved SUP permit may provide further discharge restrictions.

Based upon the anticipated water takings being discharged to the City sewer system, it's Paterson's opinion that the water discharged will not cause negative impacts to the natural environment. As the discharged water is not being returned directly to the natural environment, there are no negative effects expected related to the temperature of the discharged water. The location and operation of the appropriate discharge measures are the responsibility of the contractor.

4.0 POTENTIAL IMPACTS

4.1 Adverse Effects on Adjacent Structures

The subsurface profile at the subject site is generally comprised fill material overlain by sandy silt/silty sand and/or clayey silt layers followed by glacial till and bedrock. The majority of the expected groundwater infiltration will be encountered within the sandy silty sand/sandy silt, glacial till and bedrock. The potential dewatering volumes due to groundwater infiltration into excavation footprints are anticipated to be low to moderate dependant on location across the site and majority composition of the materials at a given location. The structures in the surrounding area typically consist of low-rise residential dwellings and are expected to be founded on silty sand/sandy silt, glacial till or bedrock. The compressibility of the silty sand/sandy silt, glacial till and bedrock in the area as a result of dewatering is anticipated to be minimal. Furthermore, dewatering is expected to be short term in duration, given the nature of the proposed development. As such, any effects related to ground surface settlement due to the water taking activities are anticipated to be negligible.

It is not expected mitigation methods will be required related to potential adverse effects on structures or infrastructure adjacent to the excavations due to the short term nature of the construction, theoretical radius of influence and compressibility of the overburden. However, mitigation methods would consist of halting pumping and providing monitoring of the potential settlement to determine if the negative effects are related to the dewatering program. If the dewatering is causing the consolidation/settlement effects, then a revised dewatering program to reduce the taking of water or providing a water recharge system to reduce the consolidation effects would be necessary.

Due to the currently proposed construction activities at the subject site (demolition, hoe-ramming, controlled blasting, shoring installations), a pre-construction survey is recommended to be carried out for the structures immediately surrounding the site to document existing conditions. It is additionally recommended in the Paterson geotechnical Report PG5231-1 dated May 12, 2020.

4.2 Adverse Effects on Neighbouring Water Wells

A search of the Ontario Water Well Records database indicates there are a large number of wells within 500 m of the site as depicted in Figure 2.3 by others included in Appendix 1. However, these wells are predominantly monitoring well installations or abandoned wells. It should be noted that 2 groundwater supply wells were identified east of the Rideau River and located well outside the theoretical radius of influence.

Furthermore, the area surrounding the site is serviced by municipal water supplies. Therefore, dewatering activities at the site are therefore not expected to cause any interference to the water supply of surrounding properties or other negative impacts.

Municipal water is available in the immediate area. However, in the event that the taking of water is shown to cause negative impacts to the water supplies of unknown existing users/sources that were in use prior to construction, the owner shall take action to make available a supply of water equivalent in quality and quantity of their typical takings, or shall compensate those affected for reasonable costs for doing so, or shall reduce water taking amounts to alleviate the negative impacts. The owner shall provide temporary water supplies, to those affected, to meet their typical takings or compensate such persons for reasonable costs associated to do so until permanent restoration of the affected water supply or an equivalent source.

4.3 Soil, Surface Water and Groundwater

A search of the MECP Brownfields Environmental Site Registry was conducted as part of the assessment of the site, neighbouring properties and the general area. No Brownfield sites were located within 500 m of the subject site.

Following the completion of a Phase II Environmental Site Assessment (ESA) by others at the subject site, it was determined that all groundwater samples analysed for metals, VOCs, PHCs and PAHs were in compliance with MECP Table 3 standards. Fill material impacted with mercury concentrations as well as electrical conductivity and sodium adsorption ratio exceeding MECP Table 3 standards have been identified on the subject site. Native soil impacted with benzo(a)pyrene and fluoranthene concentrations as well as electrical conductivity was also encountered on the property. The site is not considered to be in compliance with the O.Reg. 153/04 criteria for the proposed land use and requires a soil remedial/removal program.

It is anticipated that the material on site will be disposed of as per the MECP policy, *Management of Excess Soil - A Guide for Best Management Practices* dated January, 2014.

With respect to nearby surface water bodies, the Rideau River is located approximately 80 m to the north, 110 m to the east and 350 m to the south from the subject site due to meandering nature of the watercourse. Given the location of the river, it's located well outside the theoretical radius of influence that will develop as a result of the water taking at the subject site. As such, adverse effects to surface water features resulting from dewatering activities at the subject site are expected to be negligible.

The groundwater that is pumped from the site excavation must be managed in an appropriate manner. The contractor will be required to implement a water management program to dispose of the pumped water. It is expected the groundwater will be discharged to the City of Ottawa sewer system in accordance with the City Sewer Use By-Laws. Dependant upon the results of the baseline test to be performed for the discharge permit application, the City of Ottawa will determine the appropriate discharge location (storm versus sanitary sewer), on-site treatment or if off-site disposal is required.

4.4 Adjacent Permits to Take Water

It is understood that Robinson Village LPIV Limited Partnership has an EASR in place for the proposed water taking at the subject site and is for construction dewatering with a maximum taking of 400,000 L/day.

A search of the MECP Permit to Take Water database provided no active PTTW within 500 m of the subject site. A search of the MECP Environmental Activity and Sector Registry (EASR) database also provided no additional registries within 500 m of the subject site.

Given there are no active PTTW within 500 m of the subject site, the risk of cumulative impacts resulting from multiple PTTW in close proximity to each other is considered negligible.

5.0 STATEMENT OF LIMITATIONS

The recommendations provided in this report are in accordance with our present understanding of the project.

A hydrogeological review of this nature is a limited sampling of a site. The recommendations are based on information gathered at the specific test locations and can only be extrapolated to an undefined limited area around the test locations. Should any conditions at the site be encountered which differ from those at the test locations, we request notification immediately in order to permit reassessment of our recommendations.

The present report applies only to the project described in this document. Use of this report for purposes other than those described herein or by person(s) other than Robinson Village LPIV Limited Partnership, TC United Development, or their agent(s) is not authorized without review by Paterson Group for the applicability of our recommendations to the altered use of the report.

SYMBOLS AND TERMS

SOIL DESCRIPTION

Behavioural properties, such as structure and strength, take precedence over particle gradation in describing soils. Terminology describing soil structure are as follows:

Desiccated	-	having visible signs of weathering by oxidation of clay minerals, shrinkage cracks, etc.
Fissured	-	having cracks, and hence a blocky structure.
Varved	-	composed of regular alternating layers of silt and clay.
Stratified	-	composed of alternating layers of different soil types, e.g. silt and sand or silt and clay.
Well-Graded	-	Having wide range in grain sizes and substantial amounts of all intermediate particle sizes (see Grain Size Distribution).
Uniformly-Graded	-	Predominantly of one grain size (see Grain Size Distribution).

The standard terminology to describe the relative strength of cohesionless soils is the compactness condition, usually inferred from the results of the Standard Penetration Test (SPT) 'N' value. The SPT N value is the number of blows of a 63.5 kg hammer, falling 760 mm, required to drive a 51 mm O.D. split spoon sampler 300 mm into the soil after an initial penetration of 150 mm. An SPT N value of "P" denotes that the split-spoon sampler was pushed 300 mm into the soil without the use of a falling hammer.

Compactness Condition	'N' Value	Relative Density %
Very Loose	<4	<15
Loose	4-10	15-35
Compact	10-30	35-65
Dense	30-50	65-85
Very Dense	>50	>85

The standard terminology to describe the strength of cohesive soils is the consistency, which is based on the undisturbed undrained shear strength as measured by the in situ or laboratory shear vane tests, unconfined compression tests, or occasionally by the Standard Penetration Test (SPT). Note that the typical correlations of undrained shear strength to SPT N value (tabulated below) tend to underestimate the consistency for sensitive silty clays, so Paterson reviews the applicable split spoon samples in the laboratory to provide a more representative consistency value based on tactile examination.

Consistency	Undrained Shear Strength (kPa)	'N' Value
Very Soft	<12	<2
Soft	12-25	2-4
Firm	25-50	4-8
Stiff	50-100	8-15
Very Stiff	100-200	15-30
Hard	>200	>30

SYMBOLS AND TERMS (continued)

SOIL DESCRIPTION (continued)

Cohesive soils can also be classified according to their "sensitivity". The sensitivity, St, is the ratio between the undisturbed undrained shear strength and the remoulded undrained shear strength of the soil. The classes of sensitivity may be defined as follows:

Low Sensitivity:	St < 2
Medium Sensitivity:	2 < St < 4
Sensitive:	$4 < S_t < 8$
Extra Sensitive:	8 < St < 16
Quick Clay:	St > 16

ROCK DESCRIPTION

The structural description of the bedrock mass is based on the Rock Quality Designation (RQD).

The RQD classification is based on a modified core recovery percentage in which all pieces of sound core over 100 mm long are counted as recovery. The smaller pieces are considered to be a result of closely-spaced discontinuities (resulting from shearing, jointing, faulting, or weathering) in the rock mass and are not counted. RQD is ideally determined from NQ or larger size core. However, it can be used on smaller core sizes, such as BQ, if the bulk of the fractures caused by drilling stresses (called "mechanical breaks") are easily distinguishable from the normal in situ fractures.

RQD % ROCK QUALITY

90-100	Excellent, intact, very sound
75-90	Good, massive, moderately jointed or sound
50-75	Fair, blocky and seamy, fractured
25-50 0-25	Poor, shattered and very seamy or blocky, severely fractured Very poor, crushed, very severely fractured

SAMPLE TYPES

SS	-	Split spoon sample (obtained in conjunction with the performing of the Standard Penetration Test (SPT))
TW	-	Thin wall tube or Shelby tube, generally recovered using a piston sampler
G	-	"Grab" sample from test pit or surface materials
AU	-	Auger sample or bulk sample
WS	-	Wash sample
RC	-	Rock core sample (Core bit size BQ, NQ, HQ, etc.). Rock core samples are obtained with the use of standard diamond drilling bits.

SYMBOLS AND TERMS (continued)

PLASTICITY LIMITS AND GRAIN SIZE DISTRIBUTION

WC%	-	Natural water content or water content of sample, %
LL	-	Liquid Limit, % (water content above which soil behaves as a liquid)
PL	-	Plastic Limit, % (water content above which soil behaves plastically)
PI	-	Plasticity Index, % (difference between LL and PL)
Dxx	-	Grain size at which xx% of the soil, by weight, is of finer grain sizes These grain size descriptions are not used below 0.075 mm grain size
D10	-	Grain size at which 10% of the soil is finer (effective grain size)
D60	-	Grain size at which 60% of the soil is finer
Cc	-	Concavity coefficient = $(D30)^2 / (D10 \times D60)$
Cu	-	Uniformity coefficient = D60 / D10
0	•	and the second discuss the second

Cc and Cu are used to assess the grading of sands and gravels: Well-graded gravels have: 1 < Cc < 3 and Cu > 4Well-graded sands have: 1 < Cc < 3 and Cu > 6Sands and gravels not meeting the above requirements are poorly-graded or uniformly-graded. Cc and Cu are not applicable for the description of soils with more than 10% silt and clay (more than 10% finer than 0.075 mm or the #200 sieve)

CONSOLIDATION TEST

p'o	-	Present effective overburden pressure at sample depth
p'c	-	Preconsolidation pressure of (maximum past pressure on) sample
Ccr	-	Recompression index (in effect at pressures below p'c)
Сс	-	Compression index (in effect at pressures above p'c)
OC Ratio)	Overconsolidaton ratio = p'c / p'o
Void Rati	io	Initial sample void ratio = volume of voids / volume of solids
Wo	-	Initial water content (at start of consolidation test)

PERMEABILITY TEST

k - Coefficient of permeability or hydraulic conductivity is a measure of the ability of water to flow through the sample. The value of k is measured at a specified unit weight for (remoulded) cohesionless soil samples, because its value will vary with the unit weight or density of the sample during the test.

City of Ottawa - Sewer Use Program - Best Management Practices

DEWATERING UNCONTAMINATED WATER FROM CONSTRUCTION ACTIVITIES TO THE STORM SEWER

For information and assistant please direct all correspondence to Compliance Officer, Sewer Use Program 800 Green Creek Drive Ottawa ON K1J 1A6; or faxed to 613-745-9197; or scanned and emailed to SUP-PUE@ottawa.ca. Should you have any questions, please call the Sewer Use Program Duty Officer at 613-580-2424 extension 23326.

HOW TO KEEP SEDIMENTS AND POLLUTANTS OUT OF THE STORM DRAINS AND SANITARY SEWERS, AND PROTECT FISH HABITAT

Dewatering activities can occur at construction sites, during in-ground utilities maintenance, and site investigations/ assessments and cleanup. Depending on soil types and site history, stormwater and groundwater pumped from these sites may be contaminated with toxics (such as oil or solvents) and /or laden with sediments.

Discharging any water containing sediments or contaminants into a street, gutter, storm drain, or creek can pollute water, contaminate sediments and harm fish habitat. Some pollutants can also interfere with the operation of the Robert O. Pickard Environmental Centre- the City of Ottawa's wastewater treatment plant.

If sediments or contaminants from your job site enter a catch basin or storm drain system, you have violated the City of Ottawa's Sewer Use By-law (2003-514), as well as provincial and federal regulations. Offenders could be subject to fines and cleanup costs.

However, provided certain conditions are met, sites may dewater certain projects to the storm sewer under certain conditions.

TYPICAL PROJECTS THAT REQUIRE DEWATERING:

- Site Investigation/Assessment
- Construction, both large and small sites
- Foundation work
- Utilities infrastructure installation and repair
 - ✓ Electrical conduits
 - ✓ Vaults
 - ✓ Sewer line and storm drain maintenance
 - ✓ Phone lines and cable TV installation / repair
 - ✓ Tank removal

NOTE: Contaminated or impacted sites that involve Groundwater Remediation are not considered to be "dewatering" projects. The discharge of Remediated Groundwater to the storm sewer system is prohibited by the Sewer Use by-law. For more information on how to discharge remediated groundwater to the City's sewage works, contact the Sewer Use Program Duty Officer.

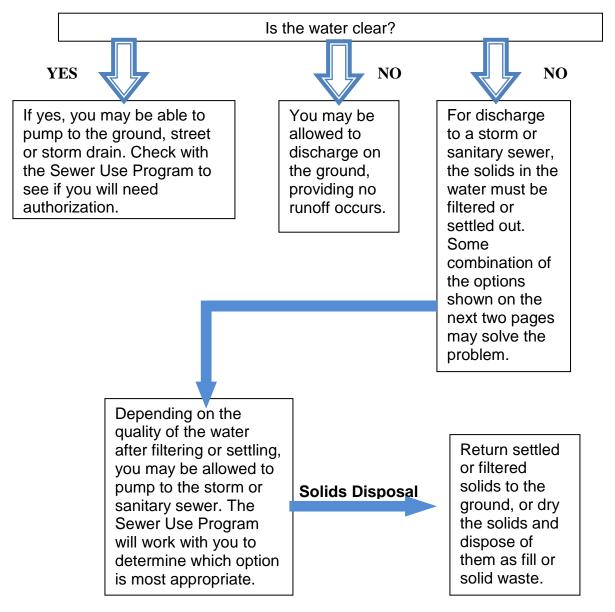

WHAT TO DO IF GROUNDWATER OR IMPOUNDED STORMWATER HAS SEDIMENTS BUT NO TOXICS ARE PRESENT

Sediments can clog storm drains, sewer lines, and smother aquatic life

HOW DO YOU DEWATER A SITE WHERE NO CONTAMINATION IS PRESENT IN THE GROUNDWATER OR IMPOUNDED STORMWATER?

ASK YOURSELF THIS QUESTION:

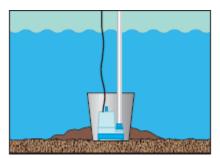

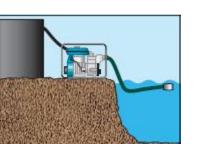

REMOVING SEDIMENTS FROM GROUNDWATER OR IMPOUNDED STORMWATER

In general, you will need to follow two steps – 1) source control; 2) filtration – to remove sediments from groundwater or impounded stormwater before you pump it off your site. Source control measures should be used before filtration. Use a combination of approaches described below for the best results. These are just some of the Best Management Practices available.

Remember to check sediment removal devices frequently to make sure they are unclogged and operating correctly. You may need to make adjustments depending on the amount of sediment in the water you're pumping.

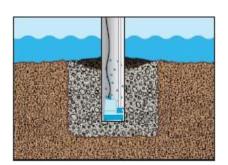

Step 1: Control sediment loading before pumping

Using a submersible pump, pump from a bucket placed below the water level.

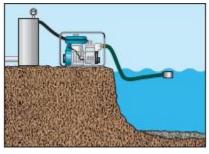

Place the end of the suction pipe on a float or similar device to draw off the top. Pump to a tank with sampling port(s).

Dig a small pit and fill with fine gravel. Pump through a perforated pipe sunk partway into the gravel.

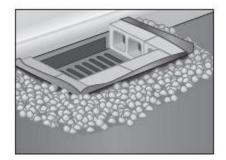

Step 2: (if necessary) Filter before final discharge Options:

Pump through a filtering device such as a swimming pool filter with the end of the suction pipe on a float or similar device.

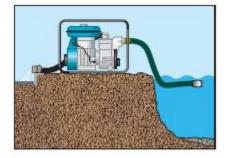

Direct water through a series of drums filled with successively finer gravel and sand.

Although not a preferred option, place filter fabric around the storm drain and anchor in place under the grate.

Surround the storm drain with concrete blocks and wrap the fabric around the outside of the blocks. Hold the fabric in place with crushed rock to complete the filtering dam.

This method is best used in conjunction with other options.

Wrap the end of the suction pipe with filter fabric and use a float or similar device to draw off the surface.

Another way to remove low levels of sediment is to discharge stormwater to a properly designed stormwater treatment facility for the type of discharge. This can include vegetated swales and/or structural devices.
