# **Technical Memorandum (Rev.3)**

Subject: 60634622 Supplementary Geotechnical Investigation at DYT3 Ottawa, Ontario

The DYT3 site (the site) is located at 2625 Sheffield Road in Ottawa, Ontario. A supplementary geotechnical field investigation program was carried out at the site between March 14 and March 15, 2022, under the full-time supervision of AECOM staff. A total of four (4) boreholes, two (2) sampled borehoels and two (2) Dynamic Core Penetration Tests (DCPTs), were advanced near the existing structure, and the borehole locations and logs are provided in **Appendix A**. The laboratory test results are provided in **Appendix B**.

#### **Subsurface Conditions at the Borehole Locations**

A granular fill layer was encountered in Boreholes BH-S1/MW and BH-S2/MW beneath the asphalt. The thickness of granular fill ranged from 76 to 180 mm. This granular fill extended to 66.92 to 66.72 metres above sea level (mASL).

A layer of sand fill underlain by a layer of granular fill was encountered in Boreholes BH-S1/MW and BH-S2/MW. The thickness of sand fill ranged from 1.2 to 1.3 m. The sand fill was encountered at the elevations ranged from 66.2 to 66.72 mASL and extended to 65.5 mASL. Standard Penetration Testing (SPT) N blow counts ranged from 10 to over 50 blows per 0.3 m of penetration, indicating a compact to very dense soil.

The native silty clay to clayey silt underlain by the layers of fill was encountered in Boreholes BH-S1/MW and BH-S2/MW. The silty clay was encountered at elevation 62.5 mASL and extended to 58.0 to 56.3 mASL. Standard Penetration Testing (SPT) N values ranged from Weight Hammer (WH) to 10 blows per 0.3 m of penetration, indicating a very soft to stiff cohesive soil. The sand seams were present within the clay layer at about 62.3mASL. According to the field vane tests at 7mbgs, the undisturbed and remolded shear strength was 34.1 kPa and 8.5kP, respectively. The sensitivity ratio was about 4. This clay was medium to very sensitive and significant settlement would be expected under loading conditions. The natural water content for the very soft clay (w=about 53.5%) was higher than the liquid limit (LL=40%), indicating a highly flocculent quick clay, i.e., the clay would liquefy when it is remolded.

The native silty clay till was underlain by a layer of native silty clay in Borehole BH-S1/MW. The silty clay till was encountered at the elevation of 58.0 mASL and it extended to 56.0 mASL. Standard Penetration Testing (SPT) N values were over 50 blows per 0.3 m of penetration, indicating a hard cohesive soil.

Bedrock was encountered in Borehole BH-S2/MW below the native silty clay materials and also in DCPT-1 and DCPT-2. The bedrock surface was encountered at elevations ranging from 57.3 to 56.3 mASL. Bedrock coring was carried out in BH-S2/MW. The bedrock is comprised of Carlsbad formation shale, which is highly weathered and in dark grey in colour with horizontal bedding. The vertical and inclined open joints were infilled with clay as were observed in the core samples. The top 2m of the shale bedrock was highly weathered with an RQD of 0% and a fracture index of about 10.

The groundwater level was observed at a depth of 4.27 mbgs at the time of drilling in the open hole. Monitoring wells were installed in Boreholes BH-S1/MW and BH-S2/MW to allow for long-term groundwater monitoring at these two locations.

#### **Foundation Options and Recommendations**

According to the historical foundation design of the building, shallow foundations have been used to support the old building. Therefore, it is feasible to use the spread footings and strip footings as the foundation design option.

#### **Foundations Options**

Typically, shallow foundations are not suitable for heavily to moderately loaded structures based on the compressible soils encountered at the site. Loading of the sensitive clay would cause significant post-construction settlement. Since the existing building is supported by shallow foundations, the soil under the existing building footprint has been consolidated. But additional loading due to an increase in building structural load will still generate some settlement. It is recommended to increase the design settlement criteria to 50mm in the Ottawa region where substantial soft soils are existing. The bearing capacities are evaluated with the detailed foundation location plan.

Based on the above considerations, the recommended option from a geotechnical/foundations perspective is to support the proposed building on spread and strip footings with a foundation depth of 1.5mbgs. The lightweight backfill is required to replace the existing and regular backfill above the footing to minimize the long-term consolidation settlement for the footings with a foundation depth of 2.7mbgs.. Otherwise, deep foundations shall be used with pile caps at 2.7mbgs.

#### **Foundation Design Capacities**

#### **Shallow foundations**

The bearing capacity at the ultimate limit state (ULS) is estimated based on the two-layer method proposed by Meyerhof and Hanna (1978) and Meyerhof (1974). The bearing capacity at the service limit state (SLS) is estimated via numerical software Settle 3 by Rocscience inc. The footings should be placed at a minimum of 1.5 m below the ground surface.

The soil layers considered in the analysis were divided into five(5) sublayers, as seen in **Table 1**. The consolidation test results are shown in **Appendix B**. The settlement analysis via Settle 3D is shown in **Appendix C**.

Unit **Consolidation Settlement Parameter Thickness** Compactness Su Φ Ε Soil Layer Weight Cv (kPa) (°) (MPa) (m) /Consistency Cc C. OCR (kN/m<sup>3</sup>) (kPa (cm<sup>2</sup>/s) Dense to very 35 52.5 dense Top silty clay with sand 1.5 Stiff to firm 20 40.0 Silty Clay 3 20 35\* 0.339 0.033 1.4 7.45E-4 Very soft Silty Clay Bottom 1 0.033 110 0.55 7.45E-4 Frim to Stiff 20 0.339 Silty Clay/Clayey Silt Till 2 Very stiff to hard 20 40.0 **Engineered Fill** 100% SPMDD 62.5 \*Weighted average value

Table 1 Soil layers for bearing capacity analysis

Based on the subsurface soil conditions described in Table 1, the bearing capacity in terms of the ULS and SLS estimated for the different sizes of spread footing is shown in Table 2. It should be noted that the footing is generally ULS controlled because

the founding soil layer is stiff to firm silty clay underlain by very soft silty clay. The ULS could be increased by subexcaving the clay and replaced with compacted engineered fill such as OPSS Granular A. At lease 0.3 m thick Granular A pad compacted at SPMDD of 100% will improve the geotechnical resistance at ULS. Geogrid (e.g., Terrafix TBX2000) between native clayey soil and granular pad will provide a better load distribution resulting in the improvement of the bearing capacity as well. It should be noted that a smaller capacity (either ULS or SLS) should be used for the foundation design.

Table 2 ULS and SLS for Shallow Foundation Option

Footing size	Factored Geotechnical Resistance at ULS (kPa)	Factored Geotechnical Resistance at ULS with 0.3 m of Granular A Pad (kPa)	Geotechnical Reaction at SLS* (kPa)
Strip footing 1.5m wide	110	115	90
2m x 2m	130	140	200
3m x 3m	120	130	150
4m x 4m	110	120	100
4m x 4m**	120	130	100**
5m x 5m	110	120	100 (General) /140 (only interior)
6m x 6m**	120	130	80**

Note: \* The SLS is calculated based on the settlement of 50mm at 15-year design life.

#### **Driven Steel H-Piles**

Steel H-piles (HP 310 x 110) can be used to support the structure. The piles will be installed through the native silty clay to clayey silt and are expected to drive into weathered bedrock. The termination elevation is anticipated at 56mASL. The pile cap elevation should be below the frost line of 1.5m below the ground surface. The in-situ load test with Pile Driving Analyzer (PDA) is needed to determine the actual capacity of the H-Pile. The factored geotechnical resistances for H-piles are shown in Table 3.

Table 3 ULS and SLS for Driven H-Pile (HP 310x110)

Pile Foundation Stratum	Estimated Tip Elevation	Approx. Design Length	Factored Geotechnical Axial Resistance at ULS (kN/Pile)	Geotechnical Axial Resistance at SLS (kN/Pile)
Bedrock (fractured)	52mASL	12 m	600*	>ULS capacity
Note: * The ULS ca	pacity should be de	termined via fiel	ld pile load test	

#### **Drilled Concrete Caissons**

To provide sufficient geotechnical resistance, the caissons should be socketed at least 2.5m into the bedrock. Temporary steel liners should be advanced to address the shallow groundwater levels and prevent caving within the wet granular soils. The following table summarizes the recommended factored geotechnical resistance at ULS and the geotechnical reaction at SLS for the caisson diameters and bearing elevation for limit states design.

Table 4 ULS and SLS for Caissons

<sup>\*\* - 2.7</sup> m embedded depth and backfill with lightweight fill. Otherwise 1.5 m embedded depth for footing and backfill with Grauluar B.

#### Resistance of Piles to Lateral Loads

The resistance to lateral loading is derived from the soil in front of the piles for vertical piles. That resistance may be estimated using Subgrade Reaction Theory (with deformations less than 5% of pile diameter), in which the coefficient of horizontal subgrade reactions  $K_S$  is based on the following equations:

In cohesionless soil:

$$K_S = n_h(z/d)$$

Where:

K<sub>S</sub> = coefficient of horizontal subgrade reaction (MPa/m)

 $n_n$  = constant of horizontal subgrade reaction (MPa/m)

d = pile diameter (m)

z = depth below ground surface (m)

In cohesive soil:

$$K_S = 67C_u/d$$

Where:

K<sub>S</sub> = coefficient of horizontal subgrade reaction (MPa/m)

C<sub>u</sub> = undrained shear strength of the soil (MPa)

d = pile diameter (m)

According to the vane test results, the undrained shear strength of the native silty clay is 34.1 kPa and 8.5kPa for undisturbed and remold strength, respectively, at this site. For the lateral resistance calculation, it is recommended that 5 kPa within the native silty clay should be used, considering the disturbance and sensitivity of the clay soil.

Lateral loading could be resisted fully or partially by use of battered piles. The piles could be installed at a better of up to 4 vertical to 1 horizontal.

Group action for lateral loading should be considered where the pile spacing in the direction of the loading is less than eight pile diameters. Group action can be evaluated by reducing the coefficient of lateral subgrade reaction in the direction of loading by a reduction fact R, as indicated in Table 5. Subgrade reaction reduction factors for other pile spacing values may be interpolated for pile spacing in between those listed in this table.

Table 5 - Lateral Load Capacity Reduction Factor for Pile Group

Pile Spacing in Direction of Loading D = Pile Diameter/Width	Subgrade Reaction Reduction Factor R
8d	1
6d	0.7
4d	0.4
3d	0.25

#### Negative Skin Friction (Downdrag Loads) on Piles

The negative skin friction within the native clay soil that are subject to settlement should be considered with the final civil/structual design. The amount of negative skin friction as well as depth to the neutral plane should be refined during the detailed design stage and based on the actual fill height, design pile length for each specific area.

#### **Lightweight Fill**

For the footings at the depth of 2.7mbgs, the Geospec@ lightweight fill EPS 22 block or equivalent shall be used as backfill materials to reduce the overall stress on the underlain compressible clay layer. The minimum replacement shall be 2.1m EPS22 lightweight fill and 0.4m granular fill/pavement structure on top of EPS 22 block. The lightweight fill shall be placed above the founding elevation and extend 0.5×B (foundation width) in all directions from the footing edge.

#### Subgrade modulus

The vertical modulus of subgrade reaction (K<sub>0.3</sub>) on the engineered fill of 30 MPa/m to 50 MPa/m (for square plate 30 x 30 cm or 30 cm wide strip resting on pre-compressed layers) may be used for the design. It should be noted that reduction of K<sub>0.3</sub> due to shape and size of foundations (i.e., Ks) should be considered.

Ks Min. K<sub>0.3</sub>= 30 Mpa/m Max. K<sub>0.3</sub>= 50 Mpa/m Mean K<sub>0.3</sub>=40 MPa/m 10.0 16.5 13.2

Table 7 Site Classification for Seismic Site Response (CFEM 2006)

Spectral accelerations and PGA values given in Table 8 should be adjusted using Tables 4.2 to 4.9 in CHBDC S6-14. The design PGA and Sa(T), should be selected based on project-specific requirements as described in the minimum performance level in CHBDC S6-14. Seismic earth pressures acting on the structure may be estimated using Mononobe-Okabe or Wood methods depending on the rigidity or tolerable movement of the structures.

Table 8 Spectral Acceleration Sa (T) and PGA (CHBDC S6-14)

#### **Liquefaction Consideration**

To delineate liquefaction susceptibility, this memo has adopted the empirical criteria recommended in the Canadian Foundation Engineering Manual:

- w/w<sub>L</sub> ≥ 0.85 and I<sub>P</sub> ≤ 12: Susceptible to liquefaction or cyclic mobility;
- $\text{w/w}_L \ge 0.80$  and  $10 \le I_P \le 12$ : Moderately susceptible to liquefaction;
- $\text{w/w}_L < 0.85 \text{ and } I_P \ge 12$ : No liquefaction or cyclic mobility.

Where w is the in-situ soil water content,  $w_L$  is the liquid limit of the soil and  $I_P$  is the plasticity index of the soil.

The clay present on site is susceptible to liquefaction as the natural water content is higher than its liquid limit.

#### **Minimum Insulation Calculation**

A design methodology for insulated foundations has been presented by Robinsky and Bespflug (1973). Summaries of their design charts for heated and unheated structures are shown in Figure 1 and Figure 2, respectively (CFEM, 2006).

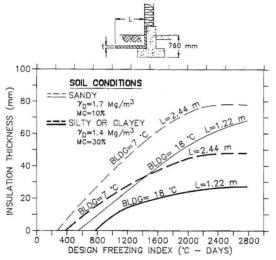

Figure 1 Design curves for minimum insulation requirments for heated structures (adapted from Robinsky and Bespflug, 1973)

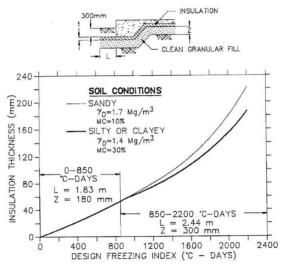

Figure 2 Design curves for minimum insulation requirments for unheated structures (adapted from Robinsky and Bespflug, 1973)

Design freezing Index of Ottawa is around 1100°C Day. As the footings will be founded on granular materials and all the backfill materials are granular materials, the sandy soil conditions are adopted while using the figures. When the building temperature of 18°C is to be maintained, Insulation should be placed with minimum soil covers of 300 mm and extend at least 1.22 m from the edge of the building. For the heated structures, the minimum installation thickness is about 20 mm according to **Figure 1**. As the perimeter of the building should be considered as unheated structures, the minimum insulation thickness is about 60 mm according to **Figure 2**.

#### **Closure**

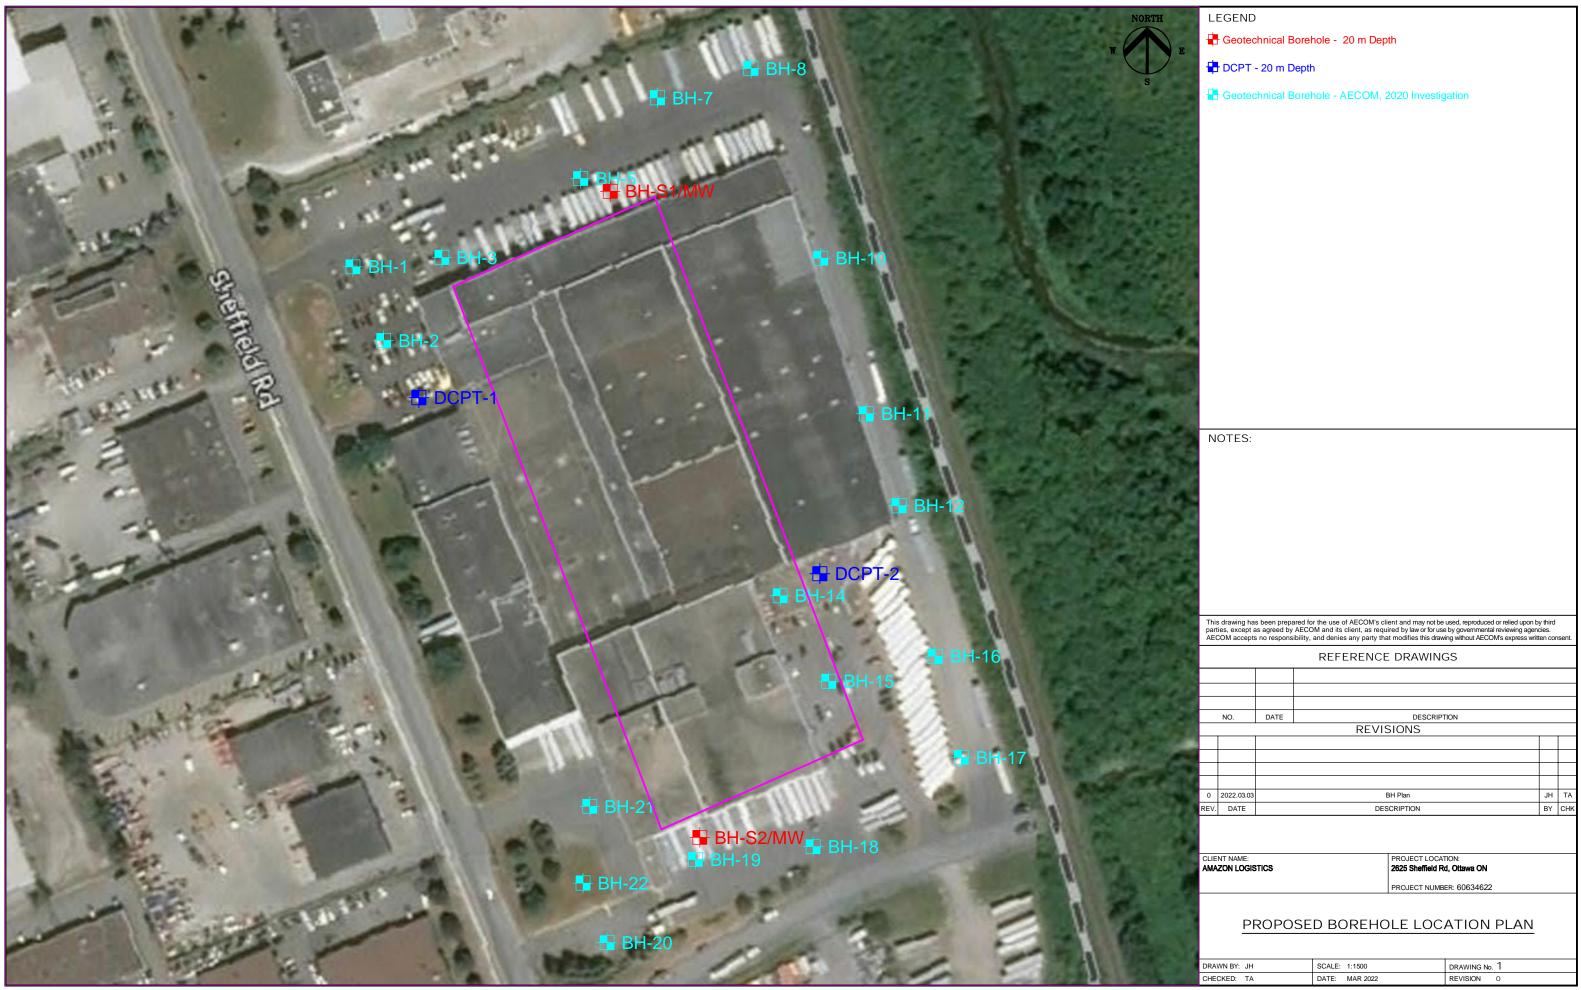

We trust that this meets your expectations. If you have any questions or need clarification, please do not hesitate to contact the undersigned.

# **Appendix A Borehole Location and Borehole Logs**

## **AECOM**

Till:

#### **TERMINOLOGY USED IN BOREHOLE LOGS**

Topsoil: Mixture of soil and humus capable of supporting

good vegetative growth.

Peat: A mass of organic matter usually fibrous in texture in various stages of decomposition,

generally dark brown to black in colour and of

spongy consistency.

concrete/steel structures.

Fill: The term fill has been used to describe materials which have been placed by non-natural processes. Fills can often be heterogeneous in nature and those relying on this report should expect them to contain deleterious materials. Such materials can include wood, bricks, slag, porcelain, organics, and obstructions such as scrap metal, storage tanks, and abandoned

Due to the uncertainty of the placement method of the material, the boring samples obtained for this report are not expected to represent other materials at any horizontal or vertical distance from where the sample was obtained.

material may Fill be contaminated by toxic/hazardous waste that renders it unacceptable for deposition in any but designated land fill site. Unless specifically stated, the fill on this site has not been tested for contaminants that can be considered toxic or hazardous. Testing to determine the toxicity of fill materials can be conducted, if requested.

The term till on the borehole logs indicates that the material originates from a geological process associated with glaciation. Till must be considered heterogeneous in composition and containing pockets and/or seams of material such as sand, gravel, silt or clay. Till often contains cobbles (60 to 200 mm) and boulders Contractors may therefore (over 200 mm). encounter cobbles and boulders durina excavation, even if they are not indicated by the logs. It should be appreciated that normal sampling equipment cannot differentiate the size or type of any obstruction. Due to the horizontal and vertical variability of till, the sample description may be applicable to a very limited zone. Caution is essential when dealing with sensitive excavations or dewatering programs in till materials.

Terminology describing soil structure

Desiccated: having visible signs of weathering by

oxidization of clay minerals,

shrinkage cracks, etc.

Stratified: alternating layers of varying material

or color with the layers greater than 6

mm thick.

Laminated: alternating layers of varying material

or color with the layers less than 6

mm thick.

Fissured: material breaks along plane of

fracture.

Varved: composed of regular alternating

layers of silt and clay.

Slickensided: fracture planes appear polished or

glossy, sometimes striated.

Blocky: cohesive soil that can be broken

down into small angular lumps which

resist further breakdown.

Lensed: inclusion of small pockets of different

soil, such as small lenses of sand scattered through a mass of clay; not

thickness.

Seam: a thin, confined layer of soil having

different particle size, texture, or color from materials above and

below.

Homogeneous: same color and appearance

throughout.

Well Graded: having wide range in grain sized and

substantial amounts of all

predominantly on grain size.

Uniformly Graded: predominantly on grain size.

Residual: completed weathered sedimentary

rock mixed with native soils.

# **AECOM**

All soil sample descriptions included in this report generally follow the Canadian Foundations Engineering Manual and the Unified Soil Classification System. These systems follow the standard proposed by the International Society for Soil Mechanics and Foundation Engineering. Laboratory grain size analyses provided by AECOM follow the same system. Note that, with exception of those samples where a grain size distribution analysis has been completed, all samples have been classified by visual inspection. Visual inspection classification is not sufficient to provide exact gain sizing.

**EQUIVALENT GRAIN DIAMETER IN MILLIMETRES** 

The standard terminology to describe cohesive soils includes consistency, which is based on undrained shear strength as measured by in-situ vane tests, penetrometer tests, unconfined compression tests or similar field and laboratory analysis. Standard Penetration Test 'N' values can also be used to provide an approximate indication of the consistency and shear strength of fine grained, cohesive soils.

The standard terminology to describe cohesionless soils includes the compactness condition as determined by the Standard Penetration Test 'N' value.

Cohesio	nless Soils		Cohesive Soil	Composition

Fracture Width (FW)

FWt Tight No visible separation FWs Slightly Open FW< 0.8 mm (1/32 in.)

FWm Moderately Open 0.8 mm (1/32 in.)≤FW<3.2 mm (1/8 in.) FWo Open 3.2 mm (1/8 in.) ≤FW<9.7 mm (3/8 in.) FWmw Moderatley Wide 9.7 mm(3/8 in.) ≤FW<25.4 mm (1 in.)

FWw Wide FW≥25.4 mm(1 in.)

Fracture Filling or Coating Thickness(FF)

FFc Clean No film coating
FFvt Very Thin FF< 0.8 mm (1/32 in.)

FFm Moderately Thin 0.8 mm (1/32 in.)≤FF<3.2 mm (1/8 in.) FFt Thin 3.2 mm (1/8 in.) ≤FF<9.7 mm (3/8 in.) FFmt Moderately Thick 9.7 mm(3/8 in.) ≤FF<25.4 mm (1 in.)

FFw Thick FF≥25.4 mm(1 in.)

Roughness

Rst Stepped Near normal steps and ridges occur on the fracture surface

Rr Rough Large angular asperities can be seen

Rm Moderately Rough Asperities are cleanly visible and fracture surface feels abrasive
Rs Slightly Rough Small asperities on the fracture surface are visible and can be felt

Rsm Smooth No asperities, smooth to the touch

Bedding Spacing (Sb)

Bm Massive  $\leq$ Sb > 3 m (10 ft)

BI Laminated SB  $\leq$  6 mm (1/4 in.)

Orientation

Of Flat =  $0 - 20^{\circ}$ Od Dipping =  $20 - 50^{\circ}$ Ov Vertical =  $50 - 90^{\circ}$ 

Surface Shape

Planar Flat surface
Wavy Undulating surface

Fracture Type:

B Bedding
J Fault
C Joint
F Foliation
S Shear Plane
M Mechanical Breaks

14. Hydraulic Conductivity (cm/sec)

15. Point Load Index:

#### Percent In Suspension (P) as per Section 14.3 of ASTM D 422

P = [(100000/W) \* (Gs/(Gs - Gw))] \* (R - Gw) in percent (for Soil Hydrometer 151 H)

Where R = Corrected Hydrometer Reading = Hs - Hc

Hs = Actual Hydrometer Reading Hc= Composite Correction to be determined as per Section 7 of ASTM D 422

#### Diameter of Soil Particles (D) as per Section 15 of ASTM D 422

 $D = SQRT \text{ of } \{[(30*\eta)/(980*(Gs-Gw)]*(L/T)\} \text{ in mm}$ 

Where  $\eta$ = Viscosity of suspending Medium (Water) in poises L = Effective Depth = L1+ 0.5\*[L<sub>2</sub> - V<sub>B</sub> /A)] in cm L1 = distance from the top of the bulb to Recorded Hydrometer Reading in cm

T = Time in minutes
