#### 1 INTRODUCTION

Kollaard Associates was retained by Luc Picknell of the Cumberland Township Agricultural Society to complete a Stormwater Management Report for the proposed fairgrounds expansion, which will consist of a 372 square metre agricultural building (barn) and 1235 square metre pavilion (open walled structure/roof canopy). The proposed agricultural building will be 100 feet (30.48m) in length by 40 feet (12.20m) in width. The proposed pavilion will be 175 feet (53.34m) in length by 75 feet (22.86m) in width. Neither of the proposed structures will be serviced and will be considered to be "dry facilities."

The report shall summarize the stormwater management (SWM) design requirements and proposed works that will address stormwater flows arising from the site under post-development conditions from both a quality and quantity perspective. The report will also describe any measures to be taken during construction to minimize erosion and sedimentation.

The site has a total area of 8.075 hectares and is currently occupied by various buildings and pavilions with associated gravel roadways and is in use by the Agricultural society. The development has been limited to a 3.879 hectare area based on the existing drainage patterns.

The subject site is accessed from Colonial Road to the north, Fairgreen Avenue to the west, and Delson Drive to the northeast. The proposed development is limited to the southern portion of the irregularly shaped parcel. Villeroy Crescent is south of the southern property line of the site, but is not accessible to the grounds.

The proposed building and pavilion will be accessed via existing gravel roadways. During events, the structures will primarily be accessed by pedestrian traffic. Additional "dry weather: parking will be provided adjacent Delson Drive within the proposed stormwater management facility, which will be further expanded on later in this report.

# 2 STORMWATER DESIGN

# 2.1 Background

The subject property for the proposed development is located along the south side of Colonial Road and the southwest side of Delson Drive. The existing ground surface is in general relatively level with a slightly higher elevation at the west end of development sloping towards the northeast. The catchment area in which the proposed structures are to be located primarily drains towards the northeast towards the roadside ditch of Delson Drive. There are also low areas, which do not drain which were observed when reviewing the topographic survey.

Runoff originating from the development area is directed to the northeast to the roadside ditch along Delson Drive.

Existing drainage patterns outside of the development area drain towards the remaining property lines via overland flow. The runoff towards the south drains to the roadside ditch of Villeroy Crescent. The runoff draining towards the north is intersected by catch basins within the existing storm network. Drainage to the west drains towards the property line via overland flow towards the property line, where it is intersected by catch basins. The existing drainage patterns outside of the development area are to remain unchanged and are outside of the scope of this stormwater management design.

The subsurface conditions at the site consist of a thin veneer of topsoil overlying fine to medium grained sand, transitioning to glacial till ad depths of between n 0.50m and 0.75m depth. During permeameter testing (to be discussed in section 2.3.12), two test holes were advanced to depths of 0.40m below the ground surface. Groundwater was not encountered in either test hole on June 25, 2024. The ground surface of the site is primarily covered with mowed grass and various trees. No plant species associated with high groundwater were observed on the site. This would indicate that the soil conditions are well draining and not subject to prolonged periods of ponding.

# 2.2 Stormwater Management Design Criteria

Design of the storm system was completed in conformance with the City of Ottawa design requirements as well as with the Ministry of Environment (MOE) Stormwater Management Planning and Design Manual (March 2003).

Quantity and quality control criteria were provided by the City of Ottawa.

The criteria are as follows:

- The post-development flow rates from the site are to ensure that runoff during the 100-year post development peak flow rate must less than or equal to the 2-year storm pre-development runoff rates.
- The pre-development runoff coefficient or a maximum equivalent 'C' of 0.5, whichever is less
- A calculated time of concentration cannot be less than 10 minutes.
- Runoff volume control should proceed with the following hierarchical order, with each step exhausted before proceeding to the next
  - Retention (infiltration, reuse, or evapotranspiration);
  - Low Impact Development Filtration, and;
  - Conventional Stormwater Management.

 An enhanced level of treatment to be provided for runoff from the site, corresponding to 80% total suspended solids removal.

# 2.2.1 Low Impact Development (LID)

The MECP LID Guide provides the following guidance with respect to Low Impact Design: Low impact development begins with the application of the principles of 'better site design' or best management practices. From a stormwater management perspective, better site design involves considering site-level opportunities and constraints to stormwater management infrastructure from the beginning of the site design process. While not all of the techniques will apply to every development, the goal is to apply as many of them as possible to maximize stormwater reduction benefits before the use of structural LID best management practice. Better site design techniques applicable to the propose development include:

- Preserving natural areas and natural area conservation;
- Stream and shoreline buffers;
- Disconnecting and distributing runoff;
- Disconnection of surface impervious cover;
- Rooftop disconnection;
- Disconnection of foundation drainage disposal from a municipal stormwater collection system;
- Reduced lot grading;
- Reduced swale slopes and increased swale cross sections where possible;

The BMPs are intended to reduce flow rates and promote filtration and the removal of sediments.

# 2.3 Stormwater Quantity Control

## 2.3.1 Methodology

Peak Flow for runoff quantities for the pre-development and post-development stages of the project were calculated using the rational method. The rational method is a common and straightforward calculation, which assumes that the entire drainage area is subject to uniformly distributed rainfall. The formula is:

$$Q = \frac{CiA}{360}$$

Where

Q is the Peak runoff measured in *m³/s*C is the Runoff Coefficient, **Dimensionless**A is the runoff area in *hectares*i is the storm intensity measure in *mm/hr* 

All values for intensity, i, for this project were derived from IDF curves provided by the City of Ottawa for data collected at the Ottawa International airport. For this project three return periods were considered, 2, 5 and 100-year events. The formulas for each are:

#### 2-Year Event

$$i = \frac{732.951}{\left(t_c + 6.199\right)^{0.810}}$$

## 5-Year Event

$$i = \frac{998.071}{\left(t_c + 6.053\right)^{0.814}}$$

#### 100-Year Event

$$i = \frac{1735.688}{\left(t_c + 6.014\right)^{0.82}}$$

Where

 $t_c$  is time of concentration in **min** *i* is the storm intensity measure in **mm/hr** 

## 2.3.2 Runoff Coefficients

Runoff coefficients for impervious surfaces (roofs, walkways and asphalt) were taken as 0.90, whereas pervious surfaces (grass) were taken as 0.20. Gravel areas have a runoff coefficient of 0.7 due to its highly compacted nature on the gravel roadways.

A 25% increase, to a maximum of 1.0 was used for the post development 100-year runoff coefficients. Refer to Appendix A for pre-development and post-development runoff coefficients.

# 2.3.3 Pre-development Conditions

As previously indicated the site has a total area of 8.075 hectares. The proposed development has been limited to a single catchment area of 3.879 hectares. The catchment area is currently occupied by four metal sided buildings, as well as 2 existing pavilions. The remaining buildings and pavilions on the site are outside of the catchment area and thus were not included in the stormwater management design. The location of the proposed barn is currently occupied by a concrete pad, which is to be retrofitted/ replaced to facilitate the proposed structure. The area of the proposed open sided pavilion is currently occupied by a compacted gravel pad.

The existing drainage patterns within the catchment area are via overland flow towards the east to the roadside ditch along the west side of Delson Drive with the exception of a small area immediately south of the gravel pad. The ground surface immediately south of the existing gravel pad, to be utilised for the proposed pavilion is currently a low area, which accepts runoff from the immediate areas and has no outlet. Following storm events, short term ponding is assumed to take place in this location and infiltrate into the native sand below. This area will be re-graded as part of the proposed development to ensure that no ponding takes place following the construction of the proposed structures.

Drawing 240297-PRE shows the pre-development conditions.

# 2.3.4 Pre-development Runoff Coefficient

The existing ground cover consisted of manicured grass, gravel roadways and various existing metal sided buildings. A detailed breakdown of the surface areas and 'C' value calculations can be found in Appendix A. The 5 year pre-development runoff coefficient was calculated to be 0.36 and the 100-year pre-development runoff coefficient is 0.44.

# 2.3.5 Pre-development Time of Concentration

The pre-development time of concentration was calculated using the airport method. The equation for the airport method is as follows:

$$tc = \frac{3.26 \times (1.1 - C) \times L^{0.5}}{S^{0.33}}$$

Where

tc is time of concentration *min*C is Rational Method runoff coefficient 0.36
L= is Flow length **m**S= catchment slope %

Using an average slope of 1.2% and a most distant flow path length of 182m, the time of concentration was calculated to be 30.39 min and was rounded to 35 minutes as a conservative estimate.

# 2.3.6 Pre-development Flow Rate

The storm intensities calculated using a time of concentration of 35 minutes and the IDF curve equations previously provided yielded 36.06 mm/hr for a 2 year storm, 48.52 mm/hr for a 5 year storm and 82.58mm/hr for a 100 year storm. Using the Rational Method with the previously calculated runoff coefficients and these storm intensities, the pre-development runoff rates for the 2-year, 5-year and 100- year storms are as follows:

```
2 year _{pre-development}= 2.78 x 0.36 x 36.06 x 3.879 = 140.0 L/s 5 year _{pre-development}= 2.78 x 0.36 x 48.52 x 3.879 = 188.4 L/s 100 year _{pre-development} = 2.78 x 0.44 x 82.58 x 3.879 = 391.8 L/s
```

## 2.3.7 Post-development Time of Concentration

A minimum time of concentration of 10 minutes is to be used for the post-development conditions.

## 2.3.8 Post-Development Site Conditions

For the purposes of this storm water management design, the site has been divided into uncontrolled and controlled areas as outlined in drawing 240297-POST (included in the appendix). Uncontrolled areas consist of areas from which runoff free flows directly off the site without restriction. Controlled areas consist of the areas from which runoff is directed by means of sheet flow, swales and subdrains to the storm water storage area from which discharge is restricted and released at a controlled rate.

The uncontrolled areas of the proposed development consist of thin strips of grassed area adjacent the property lines, as well as the portion of the gravel roadway, which currently drains to the surface of Delson Drive.

The controlled areas of the proposed development consist of the proposed and existing building areas, remaining gravel roadways and parking areas, and the landscaped areas within the catchment area defined in pre-development conditions. Runoff from this area will be directed by either sheet flow, swales, or subdrains to the proposed stormwater storage area located along the east side of the side adjacent the roadside ditch of Delson Drive.

The post-development site conditions are summarised for the site in the following Table 2-1.

Table 2-1 – Summary of Post-Development Site Conditions

#### **POST-DEVELOPMENT**

	Runoff C	Runoff Coefficient	
Description	5-year	100-year	Area (ha)
Controlled			3.809
Roof	0.90	1.00	0.426
Asphalt / Sidewalk	0.90	1.00	0
Grass	0.20	0.25	2.779
	0.70	0.88	0.604
Controlled Area Weighted Average C	0.36	0.43	
Controlled area Impervious including gravel (percentage)		27%	
Uncontrolled			0.069
Asphalt	0.90	1.00	0
Grass	0.20	0.25	0.052
Gravel	0.70	0.88	0.017
Uncontrolled Area Weighted Average C	0.32	0.41	

# 2.3.9 Post-Development Uncontrolled Area Runoff Rate

The uncontrolled runoff rate from the site consists of the flow that is directed off site from the areas without control or flow restriction. The time of concentration for the uncontrolled grass surfaced areas was taken as 10 minutes.

A post-development time of concentration of 10 minutes corresponds to a storm intensity of 76.81 mm/hr, 104.19mm/hr and 178.56mm/hr for the 2-year, 5-year and 100-year storm events respectively. Using the rational method and the above calculated runoff coefficients and rainfall intensities; the runoff rate for the combined uncontrolled areas of the site is calculated as follows:

 $Q_{2uncon}$  = 2.78 x 0.32 x 76.81 x 0.069 = 4.7 L/sec.  $Q_{5uncon}$  = 2.78 x 0.32 x 104.19 x 0.069 = 6.4 L/sec.  $Q_{100uncon}$  = 2.78 x 0.41 x 178.56 x 0.069 = 14.1 L/sec.

## 2.3.10 Post-Development Conveyance and Subdrain Design.

The runoff from the proposed barn and pavilion roof's is directed to the gravel surfaced areas adjacent the respective structures. The ground surface adjacent the proposed and existing structures slopes towards subdrained swales as shown on 240297-GR. The grading changes to the existing ground surface are to be minimal, with the major exception being the low area discussed above. This area is to be filled in to ensure that ponding does not occur in post development conditions adjacent the proposed pavilion. The subdrained swales connect to a perforated storm pipe, which will convey stormwater to the stormwater management area while simultaneously allow for infiltration within the native sand on the site.

The proposed subdrains will be placed within a clearstone trench, which has been proposed as a modified version of the City of Ottawa Standard Drawing S29 – "Perforated Pipe Installation for Rear Yard and Landscaping Applications." The subdrains will have a longitudinal slope of 0.2% as an implementation of low impact development techniques.

## 2.3.11 Implementation of LID Techniques for Quantity Control

Following the criteria for the site, and expanded on in section 2.2.1 above, Low Impact Development (LID) techniques have been implemented where possible. While the 0.2% longitudinal slope is less than what is typically proposed for conveyance of stormwater runoff, the proposed trenches in which the subdrains have been proposed are to be comprised entirely of clear stone to allow for additional short term storage areas in the event of high intensity storm events. The shallow longitudinal slope within the subdrains allows for a reduction in grading within the controlled area to promoted infiltration within the native sand, without surface ponding.

The disconnection of roof drainage and reduction in lot grading also allows for runoff from the roof areas of the proposed barn and pavilion to infiltrate in the adjacent ground surface prior to being intercepted by the stormwater management.

The proposed stormwater storage area, will also serve as an additional clear stone surfaced parking area for the site outside of rainfall events. The stormwater storage area will be expanded on further in section 2.3.13 below. The utilization of the clear stone area for parking will also result in a reduction in impervious areas.

#### 2.3.12 Permeability of Native Soils

Permeability testing was completed on the native sand materials within the areas of the proposed clear stone surfaced stormwater storage area along the northeast sides of the development area. The test results are included in Appendix A. The test results indicate that the

permeability K for the native soils at the site range from  $1.74 \times 10^{-4}$  cm/s to  $1.86 \times 10^{-4}$  cm/s. The average permeability K was taken as  $1.81 \times 10^{-4}$  cm/s. The following table obtained from Appendix C of the CVC LID guide indicates the relationship between the Percolation Time, Coefficient of Permeability and Infiltration Rate.

Table C1: Approximate relationships between hydraulic conductivity, percolation time and infiltration rate

Hydraulic Conductivity, K <sub>fs</sub> (centimetres/second)	Percolation Time, T (minutes/centimetre)	Infiltration Rate, 1/T (millimetres/hour)
0.1	2	300
0.01	4	150
0.001	8	75
0.0001	12	50
0.00001	20	30
0.000001	50	12

Source: Ontario Ministry of Municipal Affairs and Housing (OMMAH). 1997. Supplementary Guidelines to the Ontario Building Code 1997. SG-6 Percolation Time and Soil Descriptions. Toronto, Ontario.

From the above comparison, the native soils at the site would have an estimated infiltration rate of 50 mm/hr and a Percolation Time T of 12 minutes.

## 2.3.13 Allowable Post-Development Discharge Rate from the Controlled Area.

In keeping with the stormwater management criteria, the total post-development runoff rate for storms up to and including the 100-year storm event is to be less than or equal to the predevelopment runoff rate for the 2-year storm. The maximum allowable release rate from the controlled areas of the site is therefore equal to the total allowable runoff rate minus the runoff rate from the uncontrolled area of the site for each design storm event. The total allowable post-development runoff rate for the site is equal to the pre-development runoff rate.

The allowable post development runoff rates for the site are as follows:

Q<sub>controlled</sub> = Q<sub>total allowable</sub> - Q<sub>uncontrolled</sub>

For the 2-year Storm event  $\mathbf{Q}_{controlled} = 140.0 - 4.7 \text{ L/s} = 135.3 \text{ L/s}$ 

For the 5-year Storm event Q<sub>controlled</sub>= 140.0– 6.4 L/s = 133.6 L/s

For the 100-year Storm event  $\mathbf{Q}_{controlled}$ = 140.0 – 14.1 L/s = 125.9 L/s

The allowable controlled area release rate for the site is summarized in Appendix A.

# 2.3.14 Post-Development Restricted Flow and Storage

Stormwater storage for the purposes of restricting the post-development runoff rates of storms up to and including the 100-year storm event to the 2-year pre-development storm runoff will be provided within a stormwater storage area located along the east portion of the site. The proposed storage area along the east side of the site has been designed in conjunction with the quality control criteria to ensure that both the quantity and quality control criteria will be met.

It is noted that the bottom of the stormwater storage area will be between 0.70m and 1.30m above the roadside ditch. This means that there will be sufficient outlet from the storage area following storm events.

The stormwater storage area has been designed as follows:

- The clear stone surfaced storage area has a nearly flat bottom, with bottom elevations of 81.70m and 81.60m on the southwest and northeast ends respectively. The bottom width of the storage area is 22.5m, equating to a bottom slope of 0.4%. This was done to limit the amount of excavation and clear stone depth.
- A bottom length of 75 metres running parallel with the roadside ditch of Delson Drive.
- The excavation for the stormwater storage area shall extend to at least the depth of the topsoil. It is anticipated that the southwest side of the storage area will result in excavation further than the topsoil layer to achieve the proposed subgrade elevation. Should the proposed subgrade elevation along the northeast portion of the storage area be lower than the proposed underside of stone following the excavation of the topsoil, the sand removed from the southwest portion of the storage area as well as sand removed from the subdrain trenches can be used to fill the northeast side of the storage area.
- The side slopes of the excavation were assumed to be vertical. If the excavation is sloped, it will provide additional storage area for runoff.
- The clear stone surfaced storage area has a thickness of 350mm and an assumed void ratio of 0.4.
- A geotextile will be placed on the native sand layer prior to placement of the clear stone.
- The surface of the storage area was assumed to range in elevation from 82.05m at the southwest side of the clear stone surfaced area to 81.95 at the northeast end of the storage area, following the same gradient as the subgrade.
- A berm has been proposed along the northeast end side of the storage area, to restrict stormwater runoff from discharging directly into the roadside ditch without control or treatment. The berm can be constructed of either imported fill materials or utilize existing native soils on site to build up the grade adjacent the property line. The top of the berm is to have a minimum elevation of 82.40m. The side slopes of the berm were assumed to have a maximum slope of 3 units horizontal to 1 unit vertical

- The southwest side of the clear stone surfaced area is to slope back to the existing grade at a slope of 10 units horizontal to 1 unit vertical.
- Discharge from the swale will be controlled by an outlet v-notch weir plate in a concrete weir wall located within the proposed berm. The v-notch weir will have a 120 degree angle and will be set an invert of 81.98 m.
- An overflow channel will be through a rectangular weir portion over top of the v-notch weir plate with a channel width of 2.00m at an invert elevation of 82.20m
- There will be a sand filter located between the clear stone and the outlet to the roadside ditch of Delson Drive. The filter will have a subgrade elevation of 81.50, or 10cm lower than the subgrade elevation of the clear stone.
- The above mentioned berm will be constructed overtop of the sand filter. The filter will also have a height of 0.40m. Since the invert of clear stone at the outlet location is 0.3m below the ground surface at the lowest surface elevation, it will ensure that the first about 240.3 cubic metres of storage will discharge by infiltration or through the filter only.
- The surface of the clear stone storage area is to remain as clear stone and can be utilized as an additional parking area during dry weather conditions, which can be accessed from the existing gravel roadway immediately south of the storage area.
- Discharge from the storage area between the elevations of 81.60 and 81.95m will be controlled by flow through the sand filter without ponding until the filter is overtopped. Surface ponding will occur between 81.90 and 81.93, but will still discharge through the filter only. Once ponding exceeds an elevation of 81.93, the discharge will be controlled by the outlet control structure.
- The clear stone surfaced stormwater management area has been sized to ensure that the 15mm storm event, as well as the 2-year storm event can be stored entirely within the subsurface clear stone area and will discharge by means of infiltration or filter flow.
- Since there is sufficient outlet following storm events, it is anticipated that the storage area should be able to drain empty between storm events during normal circumstances
- The proposed subdrains, which will outlet into the clear stone storage area are to be constructed in accordance with the City of Ottawa's standard drawing S9 and modified as following:
  - o The trench is to be 1.20m wide
  - o The trench is to be 1.00m deep
  - A 250mm diameter perforated pipe in filter sock is to be placed 100mm above the bottom of the trench
  - The trench is to be backfilled completely with clear stone to the ground surface
  - The longitudinal slope of the subdrain is 0.2% to promote more infiltration of stormwater runoff prior to discharging into the storage facility.
  - Rear Yard Catch Basin (RYCB) ADS Nyloplast drain basins (product number 2812AG) complete with solid cover meeting H-20 (product number 1299) are to be

- installed in the locations as shown on drawing 240297 and are to be utilized for inspection and cleanout ports. Product information can be found in Appendix B.
- The outlet of the perforated subdrains is to the ground surface of the clear stone storage area at an invert of 82.05m
- The clear stone within the trenches has been included in the storage and infiltration calculation for trenches with elevations between 82.05m and 82.40m.
- The area of the trenches has been included for infiltration purposes only below elevations of 82.05

The physical characteristics of the stormwater storage area and outlet control will result in the stage - storage - discharge relationship as indicated in the following Table 2-2

Table 2-2 – Elevation, Storage and Discharge Relations

Class	Quality	Quantity		Overflow	Total	Discharge
Stage (Florestion)	Storage	Storage	Infiltration	Channel	Discharge	Outlet
(Elevation)	Volume	Volume	L/sec	Flow	L/sec	Structure
m	$m^3$	m <sup>3</sup>		L/sec		L/sec
82.40		1448.1	10.8	522.0	854.5	843.3
82.30		1142.7	9.6	184.6	376.1	366.5
82.20		856.8	8.5	0	205.8	196.8
82.10		590.2	7.4		52.6	45.1
81.98	303.3	303.3	5.3		32.0	26.6
81.95	240.3	240.3	4.2		28.0	23.8
81.90	198.7	198.7	4.0		26.2	22.2
81.80	132.5	132.5	3.7		18.9	15.1
81.70	66.2	66.2	3.4		12.7	9.2
81.60	0	0	3.1		7.4	4.3

The modified rational method was utilized to determine the maximum storage requirement within the storage swale based on the above storage discharge relationship. The calculation tables are included in Appendix A.

From the calculation tables provided in Appendix A, the maximum discharge rates and storage requirements and ponding depths for the design storm are as summarized in the following Table 2-3

Tabl	e 2-3	3 – Summar	v of Max	ximum Disc	:harge Rate	. Storage Red	auirement and	l Ponding Depth

year						

<sup>&</sup>lt;sup>1</sup> Total Outflow from the storage area includes both outlet by infiltration, filter flow and the outlet to the roadside ditch by means of the outlet structure.

From the Calculations in Appendix A as summarized in the above table, the discharge rate from the storage swale to the adjacent roadside ditch will be less than the allowable release rate for each design storm event.

# 2.4 Stormwater Quality Control

The City of Ottawa requires an enhanced level of treatment for the site. An enhanced level of treatment corresponds to 80 percent total suspended solids removal.

Stormwater treatment of 80% TSS removal will be provided by a treatment train approach. The treatment train consists of sedimentation during sheet flow over existing vegetated areas, followed by sedimentation within the clear stone areas followed by filtration through a sand filter. Pre-treatment will be provided by best management practices. Quality Control will be provided by temporary detention of the entire quality control volume generated on the controlled area. A storage swale will be constructed adjacent to the east property line. The native sand below the swale will promote infiltration. A sand filter will be constructed across the northeast side of the clear stone surfaced stormwater storage area below the outlet to provide filtration for all of the quality control volume.

Water from CA1 will travel by sheet flow and subdrains to the storage area along the northeast side of the development area. The storage swale has been designed to outlet the quality storage volume by infiltration through the native sand along the sides and bottom of the storage area and by flow through the sand filter. As a conservative approach, only infiltration

<sup>&</sup>lt;sup>2</sup> Discharge from site includes only the portion of the flow exiting the storage area by means of the outlet structure and sand filter and being directed to the adjacent roadside ditch.

<sup>&</sup>lt;sup>3</sup> The available storage considers the total of surface and subsurface storage.

through the bottom of the storage area and subdrain trenches was considered for infiltration calculations.

The Ministry of Environment Stormwater Management Planning and Design Manual (March 2003) (MOE Manual) provides guidance on design for stormwater quality control. Quality control design is completed with the fundamental understanding that the majority of sediment and particulate pollutants are washed from the site surfaces during minor (frequent) storm events. Section 3.3.1 of the MOE Manual indicates that in most cases, quality control design storms range from 12.5 mm to 25 mm. The MOE Manual also indicates that an alternate approach to the volumetric sizing of stormwater facilities for quality control has been applied in Ontario. The alternate approach is summarized in Table 3.2 Water Quality Storage Requirements Based on Receiving Waters. Table 3.2 of the MOE manual specifies the storage volume required to achieve an enhanced minimum required quality control level of treatment using infiltration or filtration.

In Part 4, the MOE Manual details the design requirements of several types of end of pipe stormwater management facilities. The proposed stormwater management design for quality control will consist of filtration. Design guidance for filtration is provided in Part 4 Section 4.6.7 Filters of the MOE Manual.

Section 4.6.7 provides the design guidance with respect to the use of a filter as summarized in the table below. A column has been added to indicate how the proposed design conforms to the Criteria.

Design Element	Design Objective	Minimum Criteria	Design Conformance	
Drainage Area		< 5 hectares	~ 3.81 hectares	
Pre-treatment	Longevity	Pre-treatment by means of sedimentation chamber, or forebay, vegetated filter strip, swale or oil/grit separator	-Vegetative filtration on grass within the landscaped areas Sedimentation within the clear stone of the subdrained swales.	
Storage Depth	Avoid Filter Compaction	Subsurface sand and organic filters: 0.5 m Maximum 1.0 m	-Maximum surface storage depth of 0.25m before overflow. Maximum total storage depth of 0.80m.	
Filter Media Depth	Filtering	Sand: 0.5 m	-Sand Filter has a minimum thickness of 0.5 m.	
Under-drain	Discharge	Minimum 100 mm perforated pipes bedded in 150 – 300 mm of 50 mm gravel	-No Under-drain provided. -Horizontal Discharge.

## 2.4.1 Volumetric Sizing and Filter Size.

The water quality storage volume requirement to achieve an enhanced level of treatment using the sand filter was determined from the MOE Manual Table 3.2 under infiltration. As previously calculated, the impervious ratio for the controlled area of the site is 27% when including gravel areas. From MOE Table 3.2, for a 35% impervious ratio at an enhanced level of treatment the storage requirement is  $25 \, \text{m}^3/\text{ha}$ .

Catchment area CA1 has an area of 3.809 ha.  $3.809 \text{ x } 25 \text{ m}^3/\text{ha}$  gives a quality storage requirement of  $95.2 \text{ m}^3$ .

The MOE Manual in section 4.6.7 under the heading Volumetric Sizing provides the following additional design guidance when using filtration for quality control:

"Water quality volumes to be used in the design are provided in Table 3.2 under the "infiltration" heading. Erosion and quantity control volumes are not applicable to this type of SWMP. The design should be such that at a minimum, the by-pass of flows should not occur below or at the peak runoff from a 4 hour 15 mm design event."

In order to ensure that by-pass would not occur below a 4 hr 15 mm design event, the clear stone surfaced stormwater storage area has been designed to accommodate the runoff volume of a 15 mm rainfall. It is noted that a runoff coefficient of 0.36 indicates that 36% of the rainfall will become runoff.

The MOE Manual indicates that the size of the filter be designed to ensure a specified volume is discharged within a specified time period using the Darcy Equation. The size of the filter and storage volume must be sufficient to ensure that no overflow or by-pass occurs below the 4 hr 15 mm design storm.

Catchment area CA1 has an area of 3.81ha. A 15mm storm event will result in a runoff volume of (3.81ha x 15mm x 0.36) = 205.7  $\,\mathrm{m}^3$  for CA1. This results in a minimum quality storage requirement of 205.7  $\,\mathrm{m}^3$ . There is a total storage volume available for quality control purposes of 240.3  $\,\mathrm{m}^3$  within the clear stone layer alone, and 303.3  $\,\mathrm{m}^3$  when including 0.03m of surface ponding before bypass.

As such the entire quality control volume required by the MOE Manual will be stored below the top of the sand filter and no by-pass or overtopping of the filter will occur below he 15mm storm event

The proposed filter has been sized based on the space available for the filter. The flow rate through the filter was calculated and the drawdown time was determined based on the volume of the quality storage in the catchment.

In CA1 the proposed filter will be constructed across the width of the storage area resulting in a length of between approximately 75 metres. The filter width will vary from 1.40m at the bottom to 0.50m at the top. The length of the filter was assumed to be constant as the water level increases.

The filter will be constructed with imported filter media sand having a percolation rate "T" time of 2 min/cm a coefficient of permeability of k = 0.1 cm/sec. Details for the sand filter have been illustrated on Kollaard Associates Inc. drawing #240297–DET–Details. The surface of the filter will be covered with a 6 ounce/yd² non-woven geotextile filter fabric (such as Terrafix 360R or an approved alternative – Included for reference in Appendix B) followed by rip-rap on the northeast side of the filter to protect the filter from erosion. The southwest side of the filter will be backfilled with the required clear stone for the storage area. This fabric offers medium

tensile strength at high elongation and good filtration, coupled with high permeability to allow for proper filtration, while holding the filter sand in place as designed.

# 2.4.2 Discharge Through Filters

The average flow rate through the sand filters was calculated using Darcy's Equation to be:

Q= A K i

A = the cross sectional area of the filter

K= coefficient of permeability

i= hydraulic gradient = head across the filter/ flow path across the filter

Calculations are provided in Appendix A.

Based on the discharge rates through the filter and by infiltration, it is expected that the draw down time in the swale for the quality control volume will be 3.6 hrs.

# 2.5 Stormwater System Operation and Maintenance

#### 2.5.1 Storm Sewers

As previously indicated, surface runoff from the catchment area will be directed by sheet flow and by subdrains to the clear stone surfaced stormwater storage area. Catch basins will be used for inspection ports and cleanouts for the subdrains which will consist of 250 mm diameter HDPE double wall pipe with smooth interior pipes. The catch basins should be inspected on a bi-monthly basis to remove debris. Sediment levels should be measured on an annual basis. When sediment builds up more than 0.3 metres it should be removed by hydrovac.

## 2.5.2 Clear Stone Surfaced Stormwater Storage Area

The clear stone surfaced stormwater storage area should be inspected on a weekly basis and after any rain fall event after construction to document whether any sediment is migrating to the clear stone storage area. Any areas of erosion or distress to the re-graded should be repaired immediately. Any excessive sediment accumulation on the clear stone surface should be removed and reported to the engineer to determine a remediation strategy.

Once vegetation of the re-graded areas is completed, it is not anticipated that any maintenance will be required for the clear stone surfaced stormwater storage area.

Inspect the clear stone area after large storm events and at least monthly for improper water drainage, berm settling, soil erosion, as well as vegetation growing within the clear stone area. Any debris and invasive plants should be removed from the storage if present.

It is anticipated that the grassed area adjacent the proposed stormwater storage area and adjacent the subdrained trenches will be disturbed as a result of the proposed development. Following the completion of construction, these areas should be reseeded to re-establish grass grown within these areas. Always water plants (grass) throughout the first year after planting until the grassed areas are fully established. The grass should be able to tolerate wet and dry conditions on their own afterwards. However, should bare or thin grass areas be encountered, over seeding may be required.

If long term ponding occurs within the storage area, the engineer should be notified. At this point the engineer could make an assessment of the material in the upper portion of the filter. If the assessment indicates that the subdrains have become compromised with sediment, the swale and filter system will require maintenance. Sub-drains would need to be replaced, and surrounding clearstone may need to be replace or washed free of silt and sediment.

#### 3 EROSION AND SEDIMENT CONTROL

An erosion and sediment control plan, appropriate to the site conditions and to the satisfaction of the City of Ottawa, will be implemented by the owner/contractor prior to undertaking any site alterations (filling, grading, removal of vegetation, etc.). The plan will be maintained during all phases of site preparation and construction in accordance with the current best management practices for erosion and sediment control. It is considered to be the owners and/or contractors responsibility to ensure that the erosion control measures are implemented and maintained.

In order to limit the amount of sediment carried in stormwater runoff from the site during construction, it is recommended to install a silt fence along the property line, as shown in Kollaard Associates Inc. Drawing #240297-ESC. The silt fence may be polypropylene, nylon, and polyester or ethylene yarn.

If a standard filter fabric is used, it must be backed by a wire fence supported on posts not over 2.0 m apart. Extra strength filter fabric may be used without a wire fence backing if posts are not over 1.0 m apart. Fabric joints should be lapped at least 150 mm (6") and stapled. The bottom edge of the filter fabric should be anchored in a 300 mm (1 ft) deep trench, to prevent flow under the fence. Sections of fence should be cleaned, if blocked with sediment and replaced if torn.

Construction activities should be timed to minimize the length of time that unprotected ground surfaces are exposed to erosive conditions. The proposed landscaping works should be

completed as soon as possible. The proposed asphaltic concrete surfaced areas should be surfaced as soon as possible.

The silt fences should only be removed once the site is stabilized and landscaping is completed.

These measures will reduce the amount of sediment carried from the site during storm events that may occur during construction.

#### 4 CONCLUSIONS

Sincerely,

This report addresses stormwater management (SWM) design requirements and proposed works that will address stormwater flows arising from the site under post-development conditions for the proposed agricultural building and proposed pavilion. Based on the analysis provided in this report, the conclusions are as follows:

Stormwater from the structures, gravel and landscaping will be directed by means of sheet flow and subdrains to a stormwater storage area along the northeast side of the development area.

The post-development runoff for storms up to and including the 100-year storm event will be restricted to less than the pre-development runoff for the 2-year storm event by means of infiltration, flow through a sand filter and outlet control through a v-notch weir.

Quality control will be provided within the clear stone surfaced stormwater storage area by means of filtration through a sand filter, infiltration and vegetative filtration on the grass surfaces adjacent the storage area.

During all construction activities, erosion and sedimentation shall be controlled.

We trust that this report provides sufficient information for your present purposes. If you have any questions concerning this report please do not hesitate to contact our office.

Calculation formulas selated to shape factor (C). Where  $H_i$  is the first water head height (cm),  $H_2$  is the second water head height (cm), a is borehole radius (cm) and  $a^n$  is microscopic capillary length factor which is decided according to the soil texture-structure category. For one-head method, only  $G_i$  needs to be calculated while for two-head method,  $G_i$  and  $G_i$  are calculated  $G_i$  and  $G_i$  are calculated  $G_i$  and  $G_i$  are  $G_i$  are  $G_i$  and  $G_i$  are  $G_i$  are  $G_i$  and  $G_i$  are  $G_i$  are  $G_i$  and  $G_i$  are  $G_i$ 

Soil Texture-Structure Category	α*(cm <sup>-1</sup> )	Shape Factor
Compacted, Structure-less, clayey or silty materials such as landfill caps and liners, lacustrine or marine sediments, etc.	0.01	$C_1 = \left(\frac{H_2/a}{2.081 + 0.121 \binom{H_2/a}{a}}\right)^{0.672}$
Soils which are both fine textured (clayey or silty) and unstructured; may also include some fine sands.	0.04	$C_1 = \left(\frac{H_1/a}{1.992 + 0.091(^{H_1}/a)}\right)^{0.683}$ $C_2 = \left(\frac{H_2/a}{1.992 + 0.091(^{H_2}/a)}\right)^{0.683}$
Most structured soils from clays through loams; also includes unstructured medium and fine sands. The category most frequently applicable for agricultural soils.	0.12	$C_1 = \left(\frac{H_1/a}{2.074 + 0.093(^{H_1}/a)}\right)^{0.754}$ $C_2 = \left(\frac{H_2/a}{2.074 + 0.093(^{H_2}/a)}\right)^{0.754}$
Coarse and gravely sands; may also include some highly structured soils with large and/or numerous cracks, macro pores, etc.	0.36	$C_1 = \left(\frac{H_1/a}{2.074 + 0.093(^{H_1}/a)}\right)^{0.754}$ $C_2 = \left(\frac{H_2/a}{2.074 + 0.093(^{H_2}/a)}\right)^{0.754}$

Calculation formulas related to one-head and two-head methods. Where R is steady-state rate of fall of water in reservoir (cm/s),  $R_{P_p}$  is Soil saturated hydraulic conductivity (cm/s),  $\Phi_m$  is Soil matric flux potential (cm/s),  $\Phi$  is Macroscopic capillary length parameter (from Table 2),  $\Phi$  is Dereble radius (cm),  $H_2$  is the first head of water established in borehole (cm) and C is Shape factor (from Table 2).

second near of water establi	sued in obvenore (cit) and	cis Shape factor (from 1 note 2).
One Head, Combined Reservoir	$Q_1 = \bar{R}_1 \times 35.22$	$K_{fs} = \frac{C_1 \times Q_1}{2\pi H_1^2 + \pi a^2 C_1 + 2\pi \left(\frac{H_1}{a^2}\right)}$
One Head, Inner Reservoir	$Q_1 = \bar{R}_1 \times 2.16$	$\Phi_m = \frac{C_1 \times Q_1}{(2\pi H_1^2 + \pi a^2 C_1)a^* + 2\pi H_1}$
Two Head, Combined Reservoir	$Q_1 = \overline{R}_1 \times 35.22$ $Q_2 = \overline{R}_2 \times 35.22$	$G_1 = \frac{H_2C_1}{\pi(2H_1H_2(H_2 - H_1) + a^2(H_1C_2 - H_2C_1))}$ $G_2 = \frac{H_1C_2}{\pi(2H_2H_2(H_2 - H_1) + a^2(H_1C_2 - H_2C_1))}$ $K_{fx} = G_2Q_2 - G_1Q_1$ $G_3 = \frac{(2H_2^2 + a^2C_2)C_1}{2\pi(2H_1H_2(H_1 - H_1) + a^2(H_1C_2 - H_2C_1))}$
Two Head, Inner Reservoir	$Q_1 = \overline{R}_1 \times 2.16$ $Q_2 = \overline{R}_2 \times 2.16$	$G_4 = \frac{(2H_1^2 + \alpha^2 C_1)C_2}{2\pi(2H_1H_2(H_2 - H_1) + \alpha^2(H_1C_2 - H_2C_1))}$ $\Phi_m = G_3Q_1 - G_4Q_2$

# **Appendix B: Product Information**

- Geotextile
- Nyloplast Catchbasins

# Terrafix 360R - Geotextile

Function: Filtration & Drainage.

Terrafix 360R is a needle-punched nonwoven geotextile made of 100% virgin polypropylene staple fibers, which are formed into a random network for dimensional stability. Terrafix 360R resists ultraviolet deterioration, rotting, biological degradation, naturally encountered alkalis and acids. Polypropylene is stable within the pH range of 2-13.

Types of applications for 360R are: Subdrains, French Drains, Foundation Drains, Trench Drains, Blanket Drains.

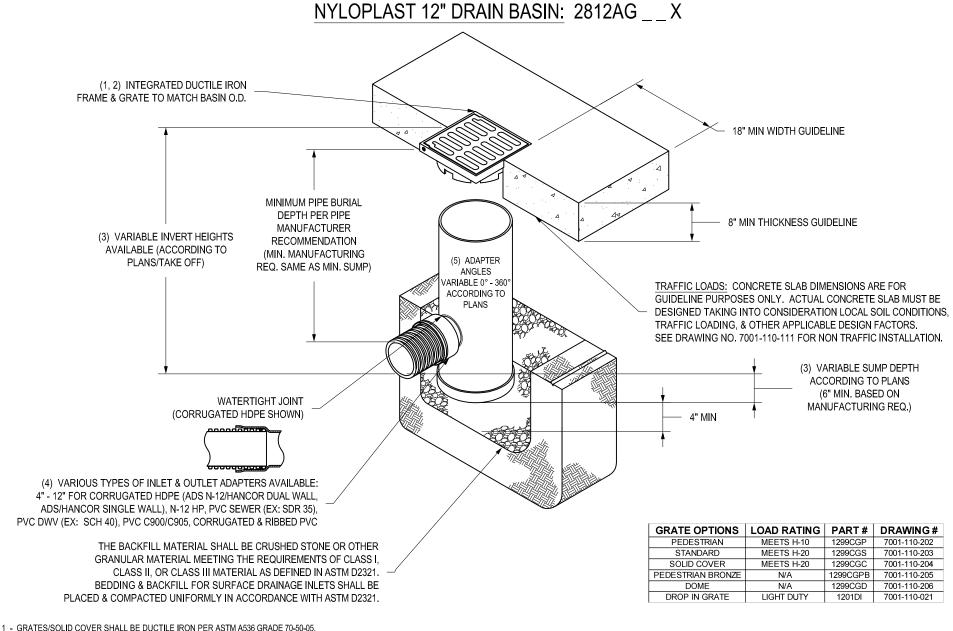

360R used in weaker soil conditions. Used in conjunction with coarser drainage materials.

Property	ASTM Test Method	Value Metric Units
Typical Geotextile Properties		
Grab Tensile Strength	D 4632	712 N
Elongation at break	D 4632	50-105%
Tear Resistance	D 4533	267 N
Puncture CBR	D 6241	1820 N
<ul> <li>Permittivity</li> </ul>	D 4491	1.5 sec <sup>-1</sup>
Water Flow	D 4491	4480 l/min/m <sup>2</sup>
Apparent Opening Size	D 4751	212 µm
• U.V. Stability	D 4355	70% @ 500hrs
• FOS	CAN 148.1 No.1	70-160 µm
