Executive Summary

Minto Communities Inc. (Minto) retained a multi-disciplinary Consultant Team to prepare a suite of comprehensive technical studies in support of the Community Design Plan (CDP) for the Barrhaven South Phase 3 – S1 Area (the S1 Area). The CDP will be implemented through an amendment to the City of Ottawa Official Plan (OP).

J.L. Richards & Associates Limited (JLR) was retained to complete an Existing Conditions Study and subsequently undertake a Master Servicing Study (MSS). The MSS demonstrates that the subject lands can be adequately serviced with municipal water, sanitary sewer, storm sewer, and stormwater management infrastructure in accordance with City of Ottawa standards and applicable provincial requirements. The recommended servicing approach confirms that sufficient capacity exists, or can be provided through planned infrastructure upgrades, to support the proposed development without adverse impacts to existing municipal systems.

The S1 Area is located immediately adjacent to the existing Barrhaven South Urban Expansion Area (BSUEA) and the Ridge Subdivision. Owing to this proximity, the MSS for the S1 Area was undertaken as an extension to the 2018 BSUEA Master Servicing Study, which was completed under the Municipal Class Environmental Assessment (EA) process as a Master Plan. As part of this EA, a comprehensive range of servicing alternatives was developed and evaluated. Accordingly, the MSS for the S1 Area was completed as an addendum to the 2018 study and is hereafter referred to as the “MSS Addendum” or “Addendum.”

This Addendum documents the technical reviews, analyses, and findings that define the preferred infrastructure servicing strategies for the S1 Area Concept Plan. The objectives of the study, as outlined in the approved Terms of Reference (Appendix A), include:

- Reviewing and inventorying existing infrastructure in the vicinity of the proposed development.
- Assessing the residual capacity of the existing water, wastewater, and stormwater infrastructure. infrastructure.
- Identifying recommended stormwater, sanitary, and water servicing solutions for the proposed development, together with design criteria to guide future detailed design.

This Addendum to Extend the Master Servicing Study has been prepared to support the Concept Plan for the S1 Area and provides a functional design solution for on-site storm drainage, wastewater collection and water distribution servicing within the S1 Area. Future draft plan of subdivision and site plan applications submitted under the Planning Act will build upon and refine the conceptual servicing solutions presented herein.

The S1 Area encompasses approximately ≈71 hectares and is bounded to the east by the Quinn’s Pointe Subdivision, to the north by the Cavain’s Greenbank Development (Ridge Subdivision), to the south by Barnsdale Road, and to the west by Borrisokane Road and Highway 416. The lands are also located adjacent to the current City of Ottawa Urban Boundary.

The Study Area consists of undeveloped lands formerly used for agricultural purposes, together with two woodlots, with the southern one identified as ecologically significant by the project biologist. The site also includes a man-excavated pond at the intersection of Borrisokane Road and Barnsdale Road, as well as an existing spill-over dry pond located in the southeast portion of the Study Area.

As part of the original BSUEA Master Servicing Study, opportunities were identified and multiple servicing alternatives were developed and evaluated to extend municipal infrastructure into the expansion area while minimizing potential impacts to the social and natural environment. The servicing strategies established through the 2018 BSUEA MSS have been extended to the S1 Area through this Addendum. The recommended servicing approach includes the following key elements:

- A conceptual storm drainage system based on a dual-drainage design approach.
- Consistent with the 2018 BSUEA MSS, the incorporation of an Etobicoke Exfiltration System (EES) along local roads, to the maximum extent practicable, where adequate separation from seasonally high groundwater levels can be achieved, while recognizing site-specific constraints under the Consolidated Linear Infrastructure Environmental Compliance Approval (CLI-ECA).
- Extension of rooftop stormwater infiltration via subsurface systems, which had previously been proposed for site plans within the BSUEA, to the industrial lands within the S1 Area.
- In areas where infiltration-based Low Impact Development (LID) measures are not feasible, implementation of a treatment train approach incorporating a filtration dry pond in Block 61 with appropriate pre-treatment measures.
- Proposed filtration dry pond adjacent to an existing spill over dry pond associated with the Quinn's Pointe Subdivision. The existing spill-over pond, originally intended to convey major overland drainage flows, will be expanded within Block 61 while maintaining the existing outlet sewer and respecting allowable flows within the downstream Quinn's Pointe storm sewer system.
- Provision of conventional storm sewers within public rights-of-way serving both residential and industrial lands. Storm sewers will be conceptually sized in accordance with the City of Ottawa Sewer Design Guidelines to convey the 1:2-year event on local roads and the 1:5-year event on collector roads.
- Assessment of residual capacity within surrounding wastewater infrastructure to identify suitable servicing outlets for sewage generated within the S1 Area. Wastewater servicing is proposed via extension of the existing sanitary sewer capped along Barnsdale Road near Bundoran Place.
- Provision of potable water servicing through watermain extensions from existing distribution systems within the Quinn's Pointe and Ridge Subdivisions.
- Confirmation that water servicing can be provided without additional interim or post-construction measures in advance of, or following, the planned municipal pressure zone reconfiguration.

This Addendum to extend the 2018 BSUEA MSS demonstrates that the development envisioned in the S1 Area Concept Plan can be serviced through strategic extensions of existing municipal water and wastewater infrastructure, together with the construction of an expanded stormwater management facility. These works will support the City of Ottawa in lifting the land-use overlay associated with the proposed Community Design Plan. The Addendum also establishes design

criteria to inform future draft plan of subdivision and site plan applications within the S1 Area. All proposed servicing works are consistent with current municipal and provincial design standards and satisfy the pre-established conditions of the CLI-ECA, thereby qualifying as pre-approved projects.

1.0 Introduction

1.1 Background

In 2016, Minto Communities Inc. (Minto) and Mattamy Homes (Mattamy) had retained a Consultant Team to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA) Community Design Plan (CDP), which was subsequently implemented as an Amendment to the City of Ottawa Official Plan (OP). As part of this undertaking, J.L. Richards & Associates Limited (JLR) had been retained to prepare a Master Servicing Study (MSS) which outlined water, wastewater, storm, and stormwater management servicing strategies for the BSUEA as well as an Existing Conditions Report that evaluated and documented existing water resources as well as the identification of servicing infrastructure in and around the BSUEA, and identified constraints and opportunities which provided the baseline conditions of an Environmental Management Plan (EMP).

The BSUEA MSS was subsequently approved by council, and a Notice of Completion of the Class Environmental Assessments (EA) was issued on August 31, 2018. Subsequently, the city was able to lift the overlay of the proposed Community Design Plan for the BSUEA. In parallel to the preparation of the 2018 MSS, parts of the BSUEA were disconnected from existing Municipal Drains, namely the Hawley and Thomas Baxter Municipal Drains, in accordance with the Ontario Drainage Act.

JLR was subsequently retained by Minto to proceed with detailed design of the various phases of the Quinn's Pointe Subdivision, which forms part of the BSUEA. To date, Stages 2 to 4 exist while the last stage of Quinn's Pointe Subdivision, namely Stage 5, is in the review process with the city's Development Review (DR).

In 2019, JLR was retained by Minto to prepare a Serviceability Study for the inclusion of several parcels located adjacent to the BSUEA. These parcels, previously referred to as the Barnsdale Expansion Lands, are located either adjacent to the current Official Plan Urban Area or in very close proximity to the Quinn's Pointe Subdivision (Stages 1-4). The 2019 Serviceability Study demonstrated that extensions from existing, and proposed infrastructure could support the urbanization of these parcels. Given their location next to the Quinn's Pointe Subdivisions (existing and future), their urbanization was deemed to be a logical urban expansion in the Barrhaven South - Barnsdale Expansion Lands.

The high-level servicing solutions presented in JLR's Serviceability Study (2019) for water, wastewater, storm and stormwater management were developed for the sole purpose of demonstrating the serviceability of each parcel. The Serviceability Study was prepared to support an application to amend the Official Plan (OP) during the City of Ottawa (City) 5-year review of the OP.

Following a review of the Serviceability Study (2019) by the City of Ottawa, two (2) of the four (4) expansion parcels that were analyzed by JLR were approved to be included in the Official Plan (OP) Urban Area; the parcels are those located north of Barnsdale Road, east and west of Greenbank Road. Specifically, this Master Servicing Study (MSS), herein as the Addendum was only prepared for one of the two (2) approved parcels, namely for the Barrhaven South Phase 3 – S1 Area.

1.2 Study and Public Participation

New urban areas added to the City's Official Plan require the preparation of Environmental Assessment (EA) Master Plans, integrated and approved under the Planning Act, to ensure coordinated land use and infrastructure planning. From a servicing perspective, the EA Master Plan should identify recommended water, sanitary, and stormwater management infrastructure, as well as transportation infrastructure (prepared by others), to support the new community.

The S1 Area is located immediately adjacent to existing Quinn's Pointe and the Ridge Subdivisions, which were part of the Barrhaven South Urban Expansion Area (BSUEA). Given this proximity, the MSS for the S1 Area was completed as an extension to the 2018 BSUEA Master Servicing Study, which was undertaken as a Municipal Class Environmental Assessment (EA) Master Plan that evaluated a range of servicing alternatives. Accordingly, this undertaking has been prepared as an Addendum to Extend the 2018 Master Servicing Study and is herein referred to as the "Addendum" or "MSS Addendum".

Under this framework, this Addendum fulfills Phase 1 (Problem and Opportunity) and Phase 2 (Alternative Solutions). Although Approach 2 typically includes a review of several servicing alternatives, these are limited, apart from those developed and evaluated under storm servicing, given that the Study Area is the last future community located in the southeast quadrant of the Barnsdale Road / Highway 416 / Borrisokane Road intersection.

As part of this Addendum, the following public consultation events have been completed to date:

- Notice of Commencement and Public Open House
- Public Open House 1 – Combined S1 & S2 (March 7, 2024)
- Public Open House 2 (May 20, 2025).

1.3 Addendum Objectives

Minto retained a Consultant Team to prepare a series of comprehensive documents that would support the Barrhaven South Phase 3 - S1 Area (herein referred to as the S1 Area). Once approved, this growth area will be implemented as an Amendment to the City of Ottawa (City) Official Plan (OP).

J.L. Richards & Associates Limited (JLR) was retained to undertake the MSS Addendum, which outlines water, wastewater, storm and stormwater management servicing strategies for the S1 Area. The Addendum demonstrates that the subject lands are serviceable with municipal water, sanitary sewer, and stormwater management infrastructure in accordance with City of Ottawa Sewer Design Guidelines and standards as well as applicable provincial requirements. The recommended servicing approach confirms that adequate capacity exists, or can be provided, to support the proposed development without adverse impacts to existing systems.

For reporting purposes, this Addendum which extends the servicing strategies identified in the 2018 BSUEA MSS will outline the preferred infrastructure servicing strategies for the S1 Area, including water, sanitary, storm sewer systems, and stormwater management.

The specific objectives of this Addendum are as follows:

- Review and prepare an inventory of the existing infrastructure surrounding the proposed development.
- Estimate residual capacity of the existing infrastructure.
- Develop conceptual site servicing for storm, stormwater management, sanitary and water services for the proposed development based on the approved Concept Plan.
- Evaluate the feasibility of conceptual servicing based on constraints and opportunities while recognizing that the proposed infrastructure will connect to existing infrastructure which had been identified as the preferred servicing solutions (per 2018 BSUEA MSS) as per the Class Environmental (Class EA) screening process.
- Select the optimal conceptual service solution for storm and stormwater management, as well as sanitary and water infrastructure.

1.4 General

Prior in preparing this Addendum that would support this new community, Terms of Reference (TOR) was prepared in accordance with the latest Ottawa Infrastructure Master Plan (IMP). The IMP provides guidance for preparing TORs for Master Servicing Studies (MSS), as outlined in "Appendix C: Guideline for Preparing Terms of Reference for a Master Servicing Study, June 2023."

JLR subsequently prepared a TOR for the S1 Area, which was accepted by the City of Ottawa. A copy of the TOR is included in Addendum for reference (Appendix A).

An Existing Conditions Report (ECR) was also prepared, with the latest version dated March 14, 2025 (sealed March 24, 2025), which is included in this Addendum (Appendix B). The ECR documented existing conditions and identified constraints and opportunities that serve as the baseline for an Environmental Impact Statement (EIS) prepared by Fotenn.

This Addendum has been prepared in support of the Concept Plan submission to confirm the servicing feasibility of the proposed development at a conceptual level. The study evaluates the proposed water, sanitary, and stormwater servicing approach associated with the Concept Plan and demonstrates that the development framework can be accommodated within the City of Ottawa's servicing standards and policies. The servicing concepts presented herein are intended to support the Concept Plan approval and to inform subsequent planning and detailed engineering design submissions, which will be subject to further review and approval by the City.

Since the proposed infrastructure within the S1 Area will connect to existing linear infrastructure in the adjacent subdivisions, as identified in the 2018 BSUEA MSS, a copy of that report is included in Appendix C for reference. This document as well as the ECR (2025) documents the servicing strategies investigated and the decision-making process that led to the selection of the recommended site servicing solutions.

Accordingly, this Addendum has been prepared in accordance with the City-approved Terms of Reference to support the Concept Plan approval process and to facilitate removal of the growth management overlay applicable to the subject lands.

1.5 Study Area

The Study Area of this Addendum encompasses ≈71 ha of an undeveloped mix of former agricultural fields and woodlots and a man-made excavated pond. The Study Area is adjacent to Barnsdale Road and Borrisokane Road to the south and west and by two (2) existing subdivisions to the east and north. It is adjacent to the Urban Boundary to the west and south (refer to Section 2.0 for more details).

1.6 Zoning and Proposed Land Use

The S1 Area is a logical development pattern, with improved phasing opportunities and more efficient connection to surrounding developments and infrastructure particularly to the Quinn's Pointe Subdivision. The S1 Area also supports the broader objectives of the city's Official Plan and will form part of the creation of a 15-minute neighbourhood with adjacent developments although not a specific requirement for this future growth area.

The Study Area includes the following three (3) types of zoning:

- Rural Countryside (RU) zone
- Agricultural Zone (AG) zone
- Mineral Aggregate Reserve (MR) zone

Based on the preferred Concept Plan (Appendix D), the proposed land usage consists of the following:

- Low density residential
- Medium density residential
- Industrial lands
- Retained woodlots[1]
- Park land
- Stormwater management block
- Servicing easements

Note [1]: The woodlot located within the Industrial and Logistics lands have been identified as a good candidate for conveyance as an urban natural feature through a future planning process. As such, this MSS has assumed the potential future conveyance of the woodlot throughout the report.

1.7 Supporting Studies

The preferred Concept Plan (Appendix D) was developed in consultation with various stakeholders and multiple city departments to support the various land uses listed in Section 1.6. The plan was prepared with consideration of constraints identified in the Environmental Impact Statement (EIS) and opportunities provided by adjacent subdivisions, as well as collector roads and the capacities of existing linear infrastructure documented in the Existing Conditions Report for the S1 Area (JLR, 2025).

Sections 3.0, 4.0, and 5.0 describe the sizing of proposed infrastructure required to support the S1 Area Concept Plan. This Addendum, completed as an extension to the 2018 Environmental

Assessment Master Plan (Master Servicing Study), was developed while considering the following supporting studies:

- Community Design Plan, Foten (2026)
- Natural Heritage Existing Conditions Report (2025), Arcadis Professional Services Canada
- Environmental Impact Statement (2026), Fotenn
- Geotechnical and Hydrogeological Existing Conditions Reports (2025), Paterson Group
- Community Energy Plan Report – Lifting of Future Neighborhood Overlay (2025), Fotenn
- Ontario Drainage Act – Revised Engineers Report (upcoming), Robinson Consultants Inc
- Sizing and Modelling of Linear Infrastructure (J.L. Richards & Associates Limited)

Regulatory approval requirements for this undertaking are listed in Section 8.0 of this Addendum.

2.0 Existing Conditions

The existing site conditions for the S1 Area were identified and outlined in JLR's 2025 Existing Conditions Report (ECR). This document included information pertaining to the site's climate, geology, physiography, drainage, surficial geology, bedrock, aquifer systems and groundwater levels, existing infrastructure at the subject site's boundary as well as additional physical attributes of the site. The latest version of the ECR is included in Appendix B of this document for reference.

2.1 Background Documents

A series of documents were reviewed as part of the 2018 BSUEA MSS, which were listed in a Synopsis of Background Documents (refer to Appendix C for the synopsis). To supplement these background documents, JLR's 2025 ECR (Appendix B) included more recent engineering documents that are applicable to Caivan's recent developments within the former aggregate extraction properties.

2.2 Surface Water Characteristics, Watercourses and Site Hydrology

The S1 Area, accounting for of ≈71 ha of land, is bounded by Quinn's Pointe Subdivision to the east, by Cavain's Greenbank Development (The Ridge Subdivision) to the north, by Barnsdale Road to the south and by Borrisokane Road to the west as shown on Figure 1 (Location Plan) is part of the Barrhaven South Area (BSC) within the former City of Nepean.

Based on the interpretation of both LiDAR data and topographical survey, the S1 Area is currently tributary to two (2) separate sub-watersheds as depicted on Figure 2 (Study Area and Drainage Divide). As shown on this figure, most of the S1 Area is tributary Mud Creek via the Thomas Baxter Municipal Drain while a small area located in the northeastern portion of the Study Area is tributary to the Jock River. Given that a significant portion of the S1 Area is tributary to a Municipal Drain, council appointed Robinson Consultants Inc. (RCI), as the Drainage Engineer, to prepare an update to the Engineer's Report to document the drainage modifications and potential disconnection from the Thomas Baxter Municipal Drain.

On-site investigations completed by the team's biologist did not identify any watercourse or formal conveyance channels within the S1 Area. The absence of channels or formal watercourses was confirmed by the review of LiDAR, which is generally indicative of areas exhibiting particularly low surface runoff potential.

Catchment areas within the S1 Area have been delineated based on LiDAR as well as surface infrastructure such as roads (which tend to form a drainage path barrier) and culverts (where flow will concentrate into a point source). Information presented in the 2025 ECR (refer to Appendix B), namely Sections 5.2 and 5.3 as well as Figure 5-2, Figure 5-3 and Figure 5-4 show the drainage areas to boundary culverts, land cover and soil types for each of the sub-catchment's that is tributary to each of the boundary culverts located along the perimeter of the site.

Hydrological modelling to establish pre-development conditions was undertaken using the SWMHYMO platform for the BSUEA as part of the 2018 MSS. Given that the analysis was undertaken to assess flows at each boundary culvert bounding both the BSUEA And S1 Area,

flows reported in the initial version (R0) of this MSS (dated October 2025) were those extracted from the 2016 ECR (BSUEA) at each of the boundary culverts under infrequent storm events.

Due to additional requirements to refine the modelling undertaken along existing roadway culverts, as part of the 2016 ECR (BSUEA), the SWMHYMO pre-development model was replaced with a pre-development model using the PCSWMM platform. Having pre-development conditions modelled in PCSWMM is consistent with the post-development PCSWMM model. The pre-development simulation results with SWMHYMO are consistent with those generated with PCSWMM and provide an estimate of flood flows at the boundary control points of the site for storm events ranging from the 1:2-year to the 1:100-year recurrence as well as for the 4-hour 25 mm storm. Section 3.13.4 of this Addendum provides refined pre- and post-development modelling using PCSWMM. Both peak flows and runoff volumes were generated for several storm events at several locations along the open diches of Borrisokane Road and Barnsdale Road as well as the headwater of the Thomas Baxter Municipal Drain.

The PCSWMM simulation results under a frequent storm (4-hour 25 mm) show relatively low flow rates at each of the boundary culverts, due to the high infiltration capacity of the native soils in the area and the low imperviousness levels. In general, during larger and less frequent events, runoff will increase as the infiltration capacity decreases due to saturation of the native soils.

PLOT DATE: Tuesday, May 26, 2026 1:26:51 PM

2.3 Site Features

The S1 Area (Figure 2) consists of an undeveloped mix of former agricultural land, two (2) woodlots, which have been identified of significance by the Team's biologist. As noted in Section 1.6 (above), the woodlot located within the Industrial and Logistics lands have been identified as a good candidate for conveyance as an urban natural feature through a future planning process. This MSS has, therefore, assumed the potential future conveyance of the woodlot throughout the report. The subject site also includes a man-excavated pond located at the intersection of Borrisokane Road and Barnsdale Road. The lands are sited adjacent to the current Urban Boundary.

The topography across the site has significant undulations. In general, the lands slope down from the northern to the southern boundary of the lands. Elevations of ±112 m at the highest point near the northern boundary while elevations drop to ±100 m at the lowest point near Barnsdale Road. At the intersection of Borrisokane Road and Barnsdale Road, in the southwest corner of the site, there is an existing man-made pond that was excavated in the 90's as displayed on the aerial on "geoOttawa".

2.4 Source Protection

The Mud Creek Subwatershed Study (2015) identified the S1 Area as being located within the Mississippi-Rideau Source Protection Region (MRSPR) as depicted in Figure 8 of the MRSPR. In addition, the entirety of the S1 Area is located within a Highly Vulnerable Aquifer based on the source protection mapping from the Ministry of the Environment, Conservation and Parks (MECP).

Conceptual storm servicing developed as part of this Addendum will incorporate infiltration measures to the maximum extent, while recognizing constraints listed in Table A2 of the Consolidated Linear Infrastructure Environmental Compliance Approval (CLI-ECA), to minimize the impact on the shallow aquifer/esker.

Section 3.10 and Section 3.11of this Addendum present recommended servicing strategies that are consistent with site specific constraints and opportunities of the Study Area. Specifically, Section 3.10 describes infiltration strategies that are proposed to the maximum extent while accounting for the constraints documented in the CLI-ECA. It should be noted that the proposed servicing strategies for the S1 Area reflect those adopted as part of the 2018 BSUEA MSS. Similarly, Section 3.11 describes the filtration strategies reviewed to the maximum extent with the preferred strategy documented in a screening process.

2.5 Geotechnical and Hydrogeological Investigations

2.5.1 General

A Geotechnical Investigation as well as a Hydrogeological Investigation were carried out by Paterson Group Inc. (Paterson) to assess general subsoil and groundwater conditions within the boundaries of the S1 Area and to provide geotechnical recommendations for the design of municipal services associated as well as sub-surface information to assess infiltration measures with the proposed development.

The latest documents prepared by Paterson are as follows:

- Existing Conditions – Geotechnical Barrhaven South Phase 3 – S1 Area (June 27, 2025)
- Hydrogeological Existing Conditions Report – Barrhaven South Phase 3 S1 Area (March 25, 2025).

Both reports have been submitted to the City by Paterson under separate cover.

2.5.2 Geotechnical

Based on the Existing Conditions – Geotechnical Barrhaven South Phase 3 (S-1 Area) report prepared by Paterson, a total of 34 boreholes and 51 test pits were completed across the site and the immediate surrounding area with limited coverage in the northern wooded area and the southwest portion of the site near the existing stormwater pond. Borehole data indicate that the overburden thickness across the site is substantial, generally ranging from approximately 15 to 25 m, and bedrock was not encountered within the depths explored. The site is predominantly underlain by non-cohesive silty sand to sandy silt, which is considered suitable subgrade material for municipal servicing.

Localized silty clay deposits were encountered within the S-1 Lands, primarily in the northwest portion of the site and in isolated areas of the central-east. These clay deposits are not continuous and occur within an otherwise granular overburden profile dominated by silty sand and sandy silt. Where present, clay is typically encountered at shallow depths of approximately 0.5 to 3.5 m below ground surface, with thicknesses generally ranging from 0.5 to 3.0 m.

From a civil servicing and grading perspective, the presence of silty clay locally governs permissible grade raise, rather than limiting the feasibility of deep servicing. The report recommends a preliminary maximum grade raise of approximately 2.5 m in areas where silty clay remains beneath settlement-sensitive infrastructure, to control long-term total and differential settlement. These restrictions apply only within clay-affected zones and do not impact most of the site, which is underlain by granular soils suitable for conventional municipal servicing. In areas where higher grade raises are required, or where servicing alignments intersect clay-affected zones, supplemental investigation and mitigation measures may be required at later stages of design.

2.5.3 Hydrogeological and Assessment of Infiltration Rates

2.5.3.1 Infiltration Characteristics and Soil Permeability

Paterson's Hydrogeological Existing Conditions Report for the S1 Area (March 2025) states that the site is predominantly underlain by non-cohesive silty sand to sandy silt overburden associated with glaciofluvial and glaciomarine deposits. These materials form an unconfined overburden aquifer with generally favourable infiltration characteristics. Hydraulic conductivity testing of the saturated overburden yielded values ranging from 4.6×10^{-7} to 4.6×10^{-5} m/s, which are consistent with moderate to high permeability soils typically associated with groundwater recharge areas and was found to be consistent those measured as part of the BSUEA.

The in-situ infiltration testing results from the report show that typical infiltration rates generally range between 50 and 100 mm/hr, with higher infiltration rates exceeding 100 mm/hr primarily

observed in the northwestern portion of the site. These elevated rates are attributed to coarser granular soils associated with the Kars Esker system. From a stormwater management and Low Impact Development (LID) perspective, these results confirm that the site is generally suitable for infiltration-based solutions, provided that adequate vertical separation to the groundwater table can be maintained. Simulated unfactored infiltration rates, for the areas intended to be serviced by an EES, is discussed in greater details in Section 3.10.3 as part of the screening process.

2.5.3.2 Groundwater Levels

From the borehole and monitoring well data presented in the Hydrogeological Report for the S1 Area (March 2025), the overburden thickness across the site is substantial, generally ranging from 15 to 25 m. Bedrock was not encountered in boreholes advanced to depths of up to approximately 17 m below ground surface, indicating that bedrock depth does not present a constraint to deep servicing infrastructure. Instead, the depth to the groundwater table represents the primary hydrogeological constraint for servicing and infiltration design.

Groundwater elevations across the S-1 Lands are relatively consistent, generally ranging from approximately 98 m to 101 m in the northern portion of the site and approximately 96 m to 99 m in the southern portion. However, due to the natural site topography, which rises from approximately 99 m near Barnsdale Road to approximately 110 m toward Kilbirnie Drive, the depth to groundwater relative to surface elevation increases toward the northern portions of the site. In these areas, groundwater levels are locally observed at depths of approximately 6 m to 12 m below ground surface, providing sufficient vertical separation to support deeper sewer infrastructure and infiltration systems, including the proposed EES system.

Conversely, the southern portion of the site exhibits shallower groundwater levels due to the lower existing surface elevation and localized perched groundwater conditions, which may constrain the feasibility and extent of infiltration-based allowances in this area.

The Hydrogeological Report provided seasonal high groundwater levels for each borehole. This data was subsequently used by Paterson to generate seasonal high groundwater contours. The compiled information was subsequently adopted as the basis for design considerations presented in this Addendum. This information has been compiled on a Figure (Figure 9a) along with other information pertaining to the proposed configuration of the EES and included in Appendix G.

2.5.3.3 Groundwater Mounding Considerations

An Etobicoke Exfiltration System (EES) was the recommended servicing solution as part of the 2018 BSUEA MSS to achieve distributed infiltration and maintain the pre-development infiltration condition. The same screening process was carried out as part of this Addendum, which has been documented in Section 3.10.3 (below). Similarly to the BSUEA, an EES is being proposed within areas underlain by coarse native materials, such as sand or sandy gravel, as was the case in the BSUEA and some of the areas within the S1 Area. There is a potential risk of groundwater mounding although more probable when native material are mostly fine-grained soils, which is not representative of the areas in the S1 Area. Nonetheless, groundwater mounding remains an important design consideration and must be evaluated to confirm system

feasibility and long-term performance in accordance with the Sewer Design Guidelines (Appendix 10). It has been reviewed in greater detail, in Section 3.10.3.

3.0 Storm Drainage and Servicing

3.1 Background

A stormwater management strategy was developed for the S1 Area to ensure that prior to any off-site discharge, runoff would meet both municipal and provincial requirements. In addition, the stormwater management strategy also requires that the integrity of the downstream systems be maintained from both a minor and major systems perspective.

The stormwater management strategy should include measures to promote infiltration, to the maximum extent, while recognizing constraints, supplemented by filtration solutions to the maximum extent. In addition to the above strategies, SWM needs is to be identified, including the facility type, size and location, along with major overland flow paths and proposed storm sewer trunks.

From a surface water perspective, the S1 Area is tributary to the following two (2) sub-watersheds as depicted on Figure 2:

- **Jock River:** A small area located in the northeast portion of the Study Area.
- **Mud Creek:** The majority of the Study Area surrounding the northeast portion.

The S1 Area is bounded by two (2) existing subdivisions and by the current urban boundary along both southern and western limits. Hence, linear infrastructure exists at the northern boundary with Caivan's Greenbank Development (The Ridge) and eastern boundary with Quinn's Pointe Subdivision (existing Stages 3 and 4 and future Stage 5).

There is an existing spill-over pond located within the S1 Area (southeastern corner). This facility was designed as part of Quinn's Pointe Subdivision with the objective of intercepting major overland flow to prevent cascading onto the future Realigned Greenbank Road, an arterial.

There is no inlet sewer originating from Quinn's Pointe Subdivision to the spill-over pond as inflow to this feature is solely via cascading of major overland flow. The spill-over pond is currently connected to Quinn's Pointe Subdivision by means of an outlet structure complete with the 900 mm diameter outlet sewer which slowly releases the captured major overland flow. Figure 3 depicts existing surface drainage conditions, including existing ponds and culverts, in the vicinity of the S1 Area.

3.2 Storm Connections and Limitations

The S1 Area is not directly connected to any receiving water course. Consequently, runoff from the Study Area will be collected and conveyed to proposed and existing storm sewers, end-of-pipe facility and/or open ditches prior to being discharged off-site within the residual capacities in the downstream systems. Figure 3 shows the internal drainage limits within the S1 Area as well as culverts located along the perimeter of the lands.

Figure 4 below shows existing and planned storm sewer servicing infrastructure surrounding the S1 Area. As indicated in Section 7.4.3 of the ECR (Appendix B), several storm sewer systems were reviewed and assessed to determine their viability in providing an outlet to the S1 Area. Based on this review, it was determined that a storm connection to Elevation Road would not be a viable option as the system does not have residual capacities to accommodate part or full flows from the S1 Area.

In terms of a connection to the open ditch system along Borrisokane Road, the storm strategy was developed to minimize sheet flow drainage from the S1 Area to that drainage system by only allowing local drainage to reach the open ditch system since it is tributary to the Thomas Baxter Municipal Drain. Ultimately, modifications to the serviced area and/or hydrological regime of the Thomas Baxter Municipal Drain will require to be documented in an update to the Engineers Report for a subsequent disconnection (either full or partial) from the Thomas Baxter Municipal Drain.

Based on existing conditions servicing, flows captured and released from the spill-over pond (located in the southeast corner of the S1 Area) is being conveyed by the Quinn's Pointe storm sewer system, consisting of storm sewers ranging between 900 mm and 1650 mm in diameters. From the downstream end of this storm sewer system, flows are released to Dry Pond 2 before discharging into the Greenbank Road trunk storm sewer system. The storm strategy presented herein meets the flow allowance along the 900 mm diameter storm sewer with Quinn's Pointe.

PLOT DATE: Tuesday, May 26, 2026 1:27:30 PM

3.3 Roadway Projects

3.3.1 Barnsdale Road Widening

In 2025, the City of Ottawa initiated a Class Environmental Assessment for the Barnsdale Road widening project, from Prince of Wales Drive to Highway 416. It is important to note that there is a section of Barnsdale that bounds the S1 Area and that will be part of the future Highway 416 interchange, an initiative led by the Ministry of Transportation (MTO), as discussed in Section 3.3.2 (below).

The above-noted undertaking will be carried out under a Schedule C Class Environmental Assessment and will examine widening options of Barnsdale Road, from a two (2) to four (4) lanes. A Transportation Environmental Study Report (ESR) will ultimately be prepared that would document outlet locations for the various sections of the roadway, along with high-level water quality and quantity measures to meet regulatory requirements. It should be noted that detailed design of the Barnsdale Road widening will need to be developed in accordance with the requirements of the City of Ottawa CLI-ECA (No 008-S701).

The servicing strategy developed and presented herein did not account for the Barnsdale Road widening project in either the storm sewers or in the end-of-pipe facility within the S1 Area. It has been assumed that drainage for the widening project would be conveyed based on the pre-development flow pattern, which is from the roadway in a southerly direction, away from the S1 Area. It is expected the roadway project would culminate through the hierarchy of the CLI-ECA (i.e. Appendix A and Table A1 and Table A2 with constraints) and could possibly integrate its own surface filtration Low Impact Development (LID) measure or Manufactured Treatment Device (MTD).

From a quantity control perspective, simulation results summarized in Section 3.13.4 have shown a decrease in both peak flows and runoff volumes released to the headwater of the Thomas Baxter Municipal Drain. Hence, an opportunity may exist to outlet some of the runoff from the widening or interchange projects (refer to Section 3.3.2 below) to the Thomas Baxter Municipal Drain and take advantage of the partial disconnection of the majority of the S1 Area as shown in Section 3.13.5.

3.3.2 Highway 416 at Barnsdale Road Interchange

A Transportation Environmental Study Report (ESR) was completed in 2023 by Morrison Hershfield. A series of alternatives were reviewed against six (6) separate criteria with Alternative 5 (Parclo AB/South Side Loop) selected as the technically preferred Alternative for the interchange configuration.

Section 5.1.4 of the Transportation ESR reads as follows:

> "*The recommended option implements a Parclo AB interchange with four (4) free flow ramps servicing movements to and from the north and two (2) inner loop ramps."*

The proposed configuration of the interchange will require the closure of roadways, including the southern portion of Borrisokane Road. Active transportation facilities are located on the north side of Barnsdale Road, with two (2) high risk potential conflict areas.

The preferred Concept Plan (Appendix D) has considered land requirements for the Highway 416 / Borrisokane Road / Barnsdale Road interchange.

3.4 Master Grading Plan

Topography varies significantly throughout the Study Area, from elevation ±109 m at the highest point near the northern boundary and drops to ±99.5 m at the lowest point near Barnsdale Road. At the northern end of the Study Area, near the Ridge Subdivision, there is a vertical difference of 4 m within a horizontal length of 100 m. Overall, there is a grade differential of approximately 10 m from the northern to the southern portion of the Study Area.

A Conceptual Grading Plan (Drawing MG1 in Appendix K) was developed, at a macro-level, for the residential portion of the S1 Area. Centerline high points, with minimum 0.1% slopes from crests to crests, were established along ROWs and corridors, to identify locations and paths for major overland flow routes. Based on the high points and respective slopes between them, assumptions were made to assess where low points could be accommodated for future roadway sag storage. Overall, a target of 70 m³/ha of storage is anticipated to be achievable, which has been incorporated into the stormwater management strategy and dual drainage PCSWMM model as described in the following sections. It should be noted that the Conceptual Grading Plan was developed to target an overall balanced of cut and fill for the residential lands rather than on a phase-by-phase basis.

There are two (2) Blocks zoned as Industrial on western part of the Study Limits, bounding Borrisokane Road, as shown on the Concept Plan (Appendix D); the Northern Block (13.22 ha) and Southern Block (3.19 ha).

Given that a Site Plan or Concept Plan was not available for these Blocks, the Master Storm (Drawing MST in Appendix K) and Master Grading (Drawing MG1) were developed for the Industrial Lands to consider the following:

- **Northern Industrial Block:** Runoff from the entire northern Industrial Block is proposed to discharge into a storm sewer system along Moyard Drive, along the storm sewer reach from STMH631 to STMH630A to STMH630 (refer to Drawings KS1 and MST in Appendix K). This receiving storm sewer consists of a traditional storm sewer supplemented by an EES, as both contributions do not require any additional quality treatment. Stormwater from this Block combined to the areas with an EES will be conveyed easterly along Moyard Drive and then southerly along Elevation Road to the proposed stormwater management dry pond located within Block 61, at STMH600, thereby by-passing the filtration dry pond.

- **Southern Industrial Block:** Runoff from the entire southern Industrial Block is proposed to discharge into a storm sewer system flowing northerly along Moyard Drive, from reach from STMH680 to STMH651 to STMH650 (refer to Drawings KS1 and MST in Appendix K). The discharge of runoff from the southern block into this storm sewer system consists of a traditional system supplemented by an EES, as contributions do require any additional quality treatment. Runoff from these will be conveyed northerly and then easterly along Moyard Drive and eventually discharge in a dedicated storm sewer system from STMH 606 to STMH605 along Elevation Road, which flows southerly to the proposed

stormwater management dry pond within Block 61, at STMH600, thereby by-passing the filtration dry pond.

As a result of the above-noted sewer servicing strategies, the northern and southern Industrial Blocks will entirely be disconnected from the Thomas Baxter Municipal Drain. In support of the urbanization of the southern Industrial Block, Minto had retained Paterson to provide guidance with this future development. A bathymetric survey and Memorandum were prepared by Paterson with geotechnical recommendations to infill the existing man-excavated pond. Refer to Appendix E for the Memorandum and Bathymetric Survey, prepared by Paterson.

3.5 Stormwater Drainage Criteria

3.5.1 General

A thorough review of relevant background reports was completed as part of the 2016 ECR supporting the BSUEA MSS. A synopsis summarizing that review was included in the BSUEA MSS (2018).

The stormwater management design target developed as part of the BSUEA MSS considered all relevant reports to the Study Area, the Existing Conditions Reports prepared by Minto's Consultant Team as well as the Ottawa Sewer Design Guidelines and MECP's Stormwater Management and Planning Manual (2003). Similarly, the adjacent S1 Area is also bound by the recommendations of the Existing Conditions Reports prepared by all Minto's sub-consultants and the following background reports:

- The Jock River Reach 2 Subwatershed Study (2009)
- Corrigan Stormwater Management Facility and Design Brief (2010).
- The Lower Rideau River Subwatershed Report (2012)
- The Mud Creek Subwatershed Study (2015)
- The Barrhaven South Urban Expansion Area Master Servicing Study (BSUEA MSS) (2018).

Given that the BSUEA MSS (2018) was prepared while accounting for the recommendations from the other four (4) studies, the S1 Area should also meet the same stormwater management criteria and design objectives along with the requirements of the latest Sewer Design Guidelines (December 2025).

The following sub-sections summarizes the stormwater management targets as follows: Section 3.5.2.2 provides details on water balance, Section 3.5.2.3 on water quality, Section 3.5.2.4 on erosion while Section 3.5.2.5 on water quantity. Similarly, minor and major systems design criteria, is described in Section 3.5.3 and Section 3.5.4, respectively.

3.5.2 Stormwater Management Design Targets

3.5.2.1 General

The stormwater management design targets established as part of the 2018 BSUEA MSS were extended to the S1 Area in accordance with this Addendum Report. Those targets were

combined with those included in the SDG (December 2025) and the city's CLI-ECA (particularly those under Appendix), in establishing the overall design criteria for the S1 Area.

3.5.2.2 Water Balance

A water balance analysis was carried out as part of the BSUEA MSS (2018) which assessed the pre- and post-development infiltration regime while accounting for the proposed infiltration measures. As part of the 2018 BSUEA MSS, a statistical analysis was completed which demonstrated that infiltration measures along local roads, sized to capture and infiltrate the 22 mm event, was sufficient to maintain the pre-development infiltration condition when supplemented with rooftop infiltration within private blocks. This strategy was also found to meet the 80% TSS removal.

The Existing Conditions Report (March 2025) included the pre-development water balance for the S1 Area, which is summarized in Section 3.6 of this document. In light of Table A2 of the CLI-ECA, the following constraints will prevent the use of the EES:

- ✓ Areas of high groundwater levels - Constraint (b)
- ✓ High Risk Activities – Constraint (e)
- ✓ Source protection Restrictions – Constraint (f)

As a result, the implementation of the EES along local roads, to the maximum extent in areas not impacted by the above-noted constraints, is to be targeted to capture/infiltrate the 22 mm event which is to be supplemented by rooftop infiltration using sub-surface systems within both Industrial Blocks.

3.5.2.3 Water Quality

Constraints identified in Section 3.5.2.2 will prevent the use of infiltration measures throughout the S1 Area. In turn, areas impacted by these constraints, will require to be serviced by LID filtration measures, to the maximum extent.

The LID filtration solution should be sized to control the storm event identified as part of a water balance analysis carried as part of the 2018 BSUEA MSS and updated in this document. Accordingly, the design target of 22 mm was used as the design capture for both LID infiltration and filtration solutions.

The proposed LID filtration solution should also achieve an 80% TSS removal, consistent with the water quality objectives associated with the Jock River. The adherence to this water quality objective can be achieved by a single servicing solution or by a combination of measures designed as a treatment train approach. As per the CLI-ECA, an 80% TSS should be targeted for the proposed filtration solution.

3.5.2.4 Erosion Control

Off-site discharges should consider erosion potential for the given sub-watershed if the point of discharge is not a storm sewer system. For any areas serviced by an EES, erosion will not be of concern as the smaller and frequent events will be captured and infiltrated. In terms of erosion for the areas serviced by the preferred LID filtration solution, the peak flows will be captured,

detained and slowly released to the dry pond. Erosion targets have been developed based on the following discharge points:

- Off-site discharge to the existing Quinn's Pointe storm sewer system will not require any special provisions as it will be limited to the discharge rates identified as part of the overall Quinn's Pointe Subdivision design, to ensure that the integrity of the storm sewer system is maintained.

- Off-site discharges to existing open ditch systems should be reviewed for both Borrisokane Road and Barnsdale Road. If both peak flows and runoff volumes have been decreased under post-development conditions (i.e., 4-hour 25 mm storm and the 1:2-year storm), erosion potential should not be of concern (refer to Section 3.13.4).

3.5.2.5 Water Quantity

Both minor and major systems should be designed to meet the criteria discussed in the sections below, including Sections 3.5.3 and 3.5.4. Given that this Addendum is developed at the functional level, assumptions were made to evaluate both minor and major systems up to the 100-year and during the climate change event (100-year + 20%) as per the SDG.

In terms of flooding, water quantity control is to be provided to limit the post-development peak flows to either the peak flow limitations of the receiving infrastructure or those under pre-development conditions.

3.5.3 Minor System

Storm sewers servicing the S1 Area are to be designed in accordance with the SDG as summarized below:

Design Capture and Level of Service

- Minimum 1:2-year and 1:5-year capture for local and collector roads, respectively.
- 1:5-year for both Industrial blocks.
- 1:10-year capture for arterial roads, transitway or any depressed driveways, where applicable.

Design Flows

- Initial sizing of storm sewers via the Rational Method design sheets with final sizing to be confirmed via a hydraulic grade line (HGL) analysis.
- Rainfall intensity-duration-frequency (IDF) statistics as per SDG.
- Time of concentration (Tc) calculated based on an inlet time of 10 minutes and 15 minutes for the industrial lands.
- Runoff coefficients (Rc) to reflect proposed development. The Rc for the S1 Area was based on recently approved developments in Quinn's Pointe and consistent with the SDG.

Design Criteria

Design Criteria as per the SDG:

- Minimum velocity 0.80 m/s
- Maximum velocity 6.0 m/s
- Manning roughness coefficient 0.013
- Minimum allowable slopes See Table 6.1 of the OSDG
- Minimum depth of cover 2.0 m
- Minor losses at manholes set in accordance with Appendix 6B of the OSDG
- Inlet control rate to be achieved with inlet control devices (ICDs) with minimum capture of 1:2 year for locals, 1:5 year for collectors and 1:10 year for arterials.

3.5.4 Major System

Storm servicing was developed following the dual drainage concept with the minor system sized based on the criteria set out in Section 3.5.3, while the major system is configured based on the criteria outlined below and evaluated in accordance with the SDG.

Road Types and Allowable Flow Depths

- Local: 350 mm at edge of pavement
- Collector: 250 mm at edge of pavement
- Urban Arterial: No barrier curb overtopping; arterial should be designed to leave one lane free of water in each direction during the 1:100-year design storm.
- In the absence of barrier curbs, flow shall not encroach into adjacent private property.

Maximum Flow Velocity on Streets

The product of velocity (m/s) and depth (m) of overland flow on streets shall not exceed 0.6 during a 1:100-year peak flow.

Major System Flow Outlets

Major system flow should be directed towards either a watercourse/ditch or to a SWMF.

3.5.5 End-of-Pipe Facility

Any end-of-pipe control measures, either dry ponds, wet ponds, or filtration dry ponds recommended in this Addendum should be conceptually sized in accordance the SDG and MOE's publication entitled "SWM Planning and Design Manual, 2003" and other relevant source of dataa.

Given that the 2008 BSUEA MSS recommended two (2) dry ponds due to significant presence of EES which results in the capture and infiltration of frequent storm events, this service option will also be extended to the S1 Area with the addition of a filtration LID solution in accordance with the CLI-ECA.

3.6 Existing Conditions Water Budget

The water budget of a given area is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. This type of analysis establishes the baseline condition and would be used to assess any future changes in infiltration to subsurface water-bearing zones. It is also used to predict changes to the hydrological cycle that will result from urbanization with LID solutions.

A continuous hydrological model is often used to understand the water budget for a given area. As described in the ECR (refer to Appendix B), the PCSWMM software platform was also used to assess the water budget as part of the BSUEA ECR and MSS competed in 2017 and 2018, respectively by JLR. Since the approach and methodology was adopted by both the City and RVCA, the PCSWMM platform and modelling approach was once again utilized for this analysis.

The water balance assessment completed for the S1 Area was based on PCSWMM's simplified groundwater and snowmelt modules that allow continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall and snowmelt.

Section 6.2 of the 2025 ECR summarized the continuous simulation results of the water budget. Specifically, Table 6-4 of the ECR (Appendix B) shows each component of the water budget which accounts for the annual precipitation depth of 864 mm. The components of the water budget were reported as followed (refer to the 2025 ECR for PCSWMM water budget modelling files):

- Evapotranspiration accounts for approximately 59% (513 mm).
- Infiltration accounts for approximately 34% (297 mm).
- Surface runoff accounts for 7% (61 mm).

Figure 5 below summarizes graphically the various components of the existing condition water budget while a more detailed breakdown is provided below as reported in the 2025 ECR.

Figure 5: Existing Conditions Water Budget

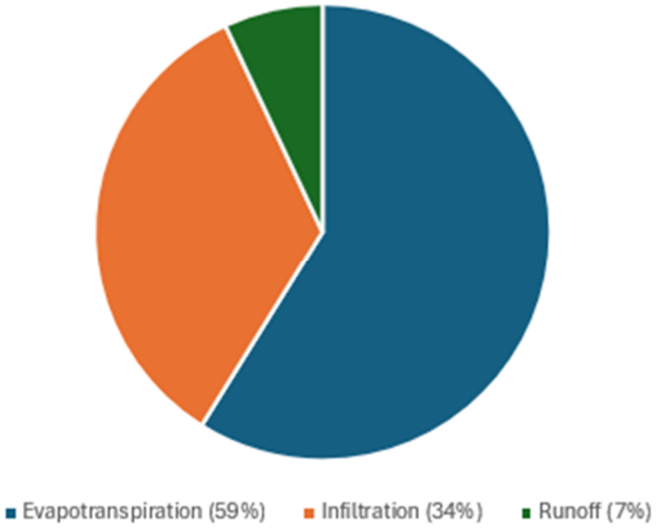

Table 1: Water Budget Continuous Simulation Results

Annual Water Budget Component	Annual Average Depth to Jock River (mm)	Annual Average Depth to Mud Creek (mm)	Annual Average Depth to Rideau River (mm)	Area Weighted Total (mm)	Budget %
Precipitation	864	864	864	864	100%
Evapotranspiration	509	531	509	513	59%
Infiltration	296	314	286	297	34%
Surface Runoff	83	60	0	61	7%

It should be noted that the Rideau River does not receive surface runoff directly from the S1 Area. However, infiltrated runoff does contribute to the groundwater catchment of the Rideau River. This is reflected in the results in the above Table.

Based on the above summary Table, infiltration under existing condition accounts for approximately 34% of the total annual precipitation of 864 mm when the three (3) receivers are combined, while surface runoff accounts for approximately 7% on a yearly average.

3.7 EES Monitoring (On-Going)

3.7.1 Monitored Rainfall Events

Monitoring of the EES was made a condition of approval within the Quinn's Pointe subdivision to gather data and confirm the suitability of the design parameters adopted during the preliminary design of the EES as part of the 2017 BSUEA. To facilitate monitoring, the city advised that it should be completed using the SmartLevel™ technology supported by Link Utility Technology as it has been tested and adopted by the City's Operation Group. In parallel, monitoring of

rainfall events was carried out using the SmartRain™ system to collect real-time precipitation data. The objective of the monitoring was as follows:

- Determine the spill occurrences and identify under which rainfall events results in spills into the conventional storm sewer system occur; and
- Determine the drawdown time and identify the time it takes for the drawdown of the EES following a rainfall event.

Three (3) monitoring locations have been set up within Quinn's Pointe Stages 2 and 3. The locations were established to cover various sizes of serviced areas; a small area at MHST82176 (2.6 ha), a mid-size area at MHST82182 (7.6 ha) and a larger serviced area at MHST83698 (20.5 ha).

Level monitoring was initiated once a minimum occupancy of 80% of the serviced area was achieved. Level monitoring was initiated in June 2022 for one of the stations while monitoring for the other two (2) stations was initiated in November 2022. Given the 22 mm capture, the review of the monitored data mainly focused on events of 22 mm or greater magnitude.

Of the 235 monitored events, twenty-seven (27) had total rainfall depths greater than 22 mm. The events greater than 22 mm depth are listed in the Table below in descending order of total rainfall depth.

Table 2: Recorded Rainfall Events (>22 mm and 0°C)

Date	Event Start	Event Duration (hrs)	Peak Intensity (mm/hr)	Total Event Rainfall Depth (mm)
August 7, 2022	2:00 PM	46	19.81	92.07
April 29, 2023	9:00 AM	122	5.33	76.83
June 6, 2024	3:00 AM	60	16.51	61.15
August 10, 2023	12:00 PM	11	28.96	58.2
August 7, 2023	8:00 AM	28	14.73	54.28
August 8, 2024	7:00 PM	22	7.62	48.63
October 30, 2025	10:00 AM	37	4.32	47.07
September 18, 2022	10:00 AM	50	12.95	38.65
August 17, 2024	1:00 AM	63	8.64	38.21
June 21, 2024	9:00 AM	74	9.91	37.88
July 9, 2024	7:00 PM	49	8.38	37.1
May 27, 2024	9:00 AM	33	12.19	33.43
April 11, 2024	8:00 AM	57	4.32	31.8
October 7, 2025	10:00 AM	16	9.4	30.9

Date	Event Start	Event Duration (hrs)	Peak Intensity (mm/hr)	Total Event Rainfall Depth (mm)
July 24, 2024	8:00 AM	13	9.4	30.2
October 6, 2023	10:00 AM	33	12.95	29.64
November 11, 2022	3:00 PM	14	5.84	29.12
July 15, 2023	9:00 PM	12	14.99	28.33
July 11, 2022	7:00 PM	24	17.78	28.27
August 28, 2025	3:00 AM	40	11.43	27.26
November 20, 2024	11:00 PM	47	2.54	27.14
July 21, 2023	12:00 AM	21	8.64	25.19
June 26, 2023	1:00 AM	22	15.24	24.98
July 18, 2022	7:00 AM	15	7.62	24.78
May 21, 2024	6:00 AM	15	14.73	24.33
July 24, 2022	12:00 PM	14	8.89	23.26
April 18, 2025	4:00 PM	18	9.65	22.26

Based on the above, the monitored events spanned, in general, between 22 mm to 92 mm with most of the events ranging between the 25 mm - 40 mm. The most significant event of 92 mm occurred over 46 hours and its 12-hour intensity was established to be comparable to a 1:10-year event when compared to the Ottawa IDF statistics.

3.7.2 EES Performance

Ten (10) out of the 27 events have resulted in flow conveyed by the traditional storm sewer, referred as a spill event. These events are considered to have occurred when the depth recorded in the manhole is above the invert elevation of the conventional sewer. Monitoring details along the three (3) monitoring stations follows (refer to Table 3 below):

- MH309: A single spill occurred on August 7, 2022, which was triggered by a 92.07 mm event.
- MH327; No spills were recorded.
- MH109: Nine (9) spill events were monitored – MH located at the intersection of Edenderry Way and Oranmore Lane.

Table 3: Spill Event Summary

Event	Location	Rainfall up to Spill Event (mm)	Duration of Spill Event (hrs)	Total Event Rainfall Depth (mm)	Drawdown Duration
August 7, 2022	MH309	22.48	5mins	92.07	2hrs 56mins
April 29, 2023	MH109	37.3	2hrs 50mins	76.83	47hrs 12mins
August 7, 2023	MH109	39.13	5hrs 41mins	54.28	56hrs 18mins
August 10, 2023	MH109	12.09	5hrs 5mins	58.2	45hrs 41mins
May 27, 2024	MH109	24.21	4hrs 16mins	33.43	231hrs 15mins
June 6, 2024	MH109	41.33	2hrs 45mins	61.15	16hrs 40mins
June 26, 2024	MH109	17.12	2hrs 25mins	17.12	55hrs
July 9, 2024	MH109	34.83	2hrs 25 mins	37.1	10hrs 10 mins
March 16, 2025	MH109	9.39	3hrs 23 mins	12.88	40hrs 50 mins
October 7, 2025	MH109	21.47	4hrs 46 mins	30.9	23hrs 47 mins

As shown above, the performance of the EES at both MH327 and MH309 by far exceed the design basis of the system, being the capture of a 22 mm rainfall event. The only recorded spill at MH309 was triggered by an event that exceeded 22 mm.

All the spills, apart from one event at MH309, occurred at MH109. The spills were triggered by storms exceeding 22 mm, except for three (3) events with rainfall of ±12 mm (August 10, 2023), ±17 mm (June 26, 2024) and ±9.4 mm (March 16, 2025). Details on these events follow:

- The August 10, 2023, event (58.2 mm) occurred less than 48 hours after the end of the August 7, 2023, rainfall event which had totaled 54.28 mm. On August 10, 2023, the slow drawdown continued, indicating elevated groundwater at that station.
- The spill events that occurred on June 26, 2024 (9:45 PM), was found to occur immediately after three (3) consecutive storms occurring between June 21st, 2024, to June 25th, 2024, totalling 55.24 mm.
- The March 16, 2025, event was during high groundwater reflecting typical spring freshet.

Based on the monitoring completed from 2022-2025, the performance of the EES in general exceeds the design capture of the system at 22 mm. However, one of the three (3) monitoring locations (MH109), has most of the spills shown in the above table. It should be noted that at that location, a separation less than 1 m (actual separation was 0.28 m) exists between the recorded seasonally high groundwater table and the bottom of the granular which explains why spills at that location are encountered more frequently.

3.7.3 Winter Performance

The annual EES monitoring Reports included graphical results showing monitoring results throughout the year including winter months, spanning from December until end of February. Although there are fewer precipitation events during this window, the data indicates that runoff from rain-on-snowmelt events, when applicable, is transmitted to the EES and infiltrated (refer to Annual EES Monitoring Reports), assuming that CB grates are fee of ice. The Table below summarizes a few winter events captured by the EES which were infiltrated.

Table 4: Winter Events Captured by EES

Date	Event Start	Event Duration (hrs)	Peak Intensity (mm/hr)	Total Event Rainfall Depth (mm)
January 9, 2024	5:00 AM	29	6.35	29.3
January 4, 2023	2:00 PM	9	4.32	13.51
December 16, 2024	8:50 PM	13	2.79	8.83

3.7.3.1 Drawdown Time During Winter Months

Based on the review of the monitoring data, it appears that drawdown of the EES (to the invert of the inlet of the EES) during winter months, continues to occur within the duration of the rainfall event or within a short period following the rainfall event based on Figures 6,7 and 8 below.

Rainfall events that occur during the winter are generally smaller in depth and have a smaller storm intensity as is expected during colder periods of the year. However, the below table and figures demonstrate that the EES continues to infiltrate during winter months event if the overall average rate of 18 mm/hr is slightly inferior to the design rates used in the MSS modelling. The design rates varied between 19.96 mm/hr to 20.63 mm/hr to 28.42 mm/hr depending on location. The rates used were as per the on-site testing results from the Geotechnical Engineers with a 2.5 factor of safety applied. Thus, the monitoring data shows a faster drawdown rate when compared to the simulated drawdown. A faster drawdown rate should allow a greater capture of the back-to-back events, which in turn, will generate greater infiltration.

Table 5: Winter Drawdown Rate Calculations (MH309)

Date	Rainfall Event depth up to Dry Period (mm)	Start Recorded Level (mm)	End Recorded Level (mm)	Dry Period Duration (hrs)	Total Event Rainfall Depth (mm/hr)
January 10, 2024, 11:00am	29.3	573	400	6.92	25
December 17, 2024, 10:10am	8.83	511	400	12.33	9
January 4, 2023, 11:00pm	13.51	585	400	9.3	20
Average Rate					18

Figure 6: Drawdown Rate Chart (January 2023 Event)

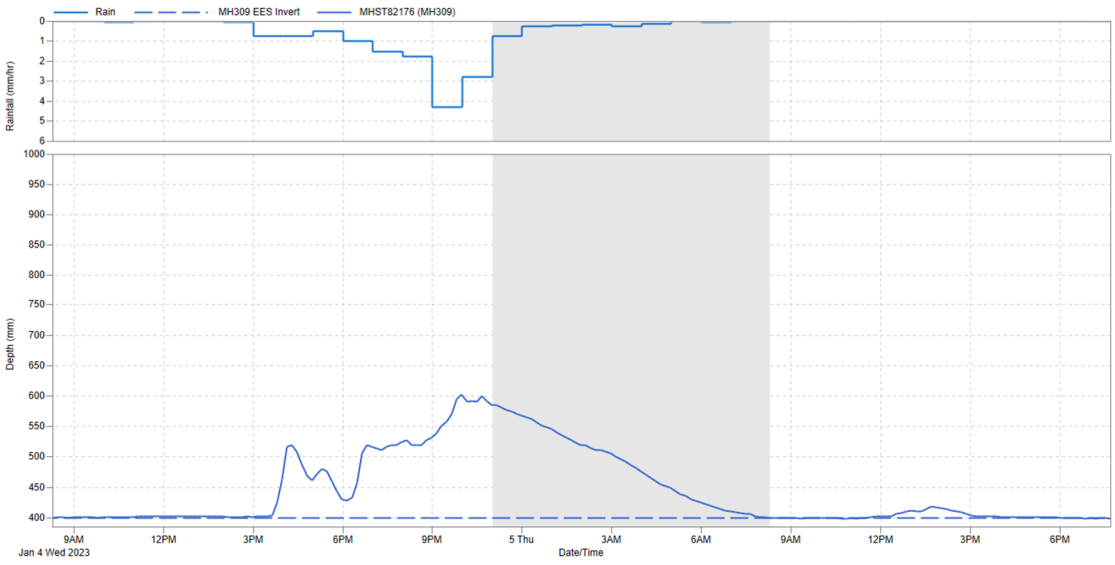

Figure 7: Drawdown Rate Chart (January 2024 Event)

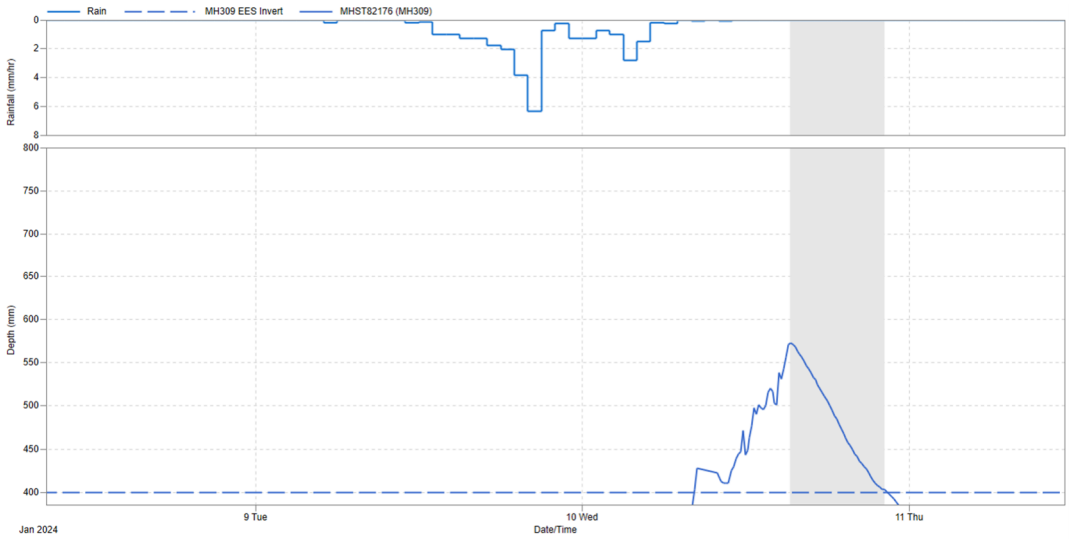

Figure 8: Drawdown Rate Chart (December 2024 Event)

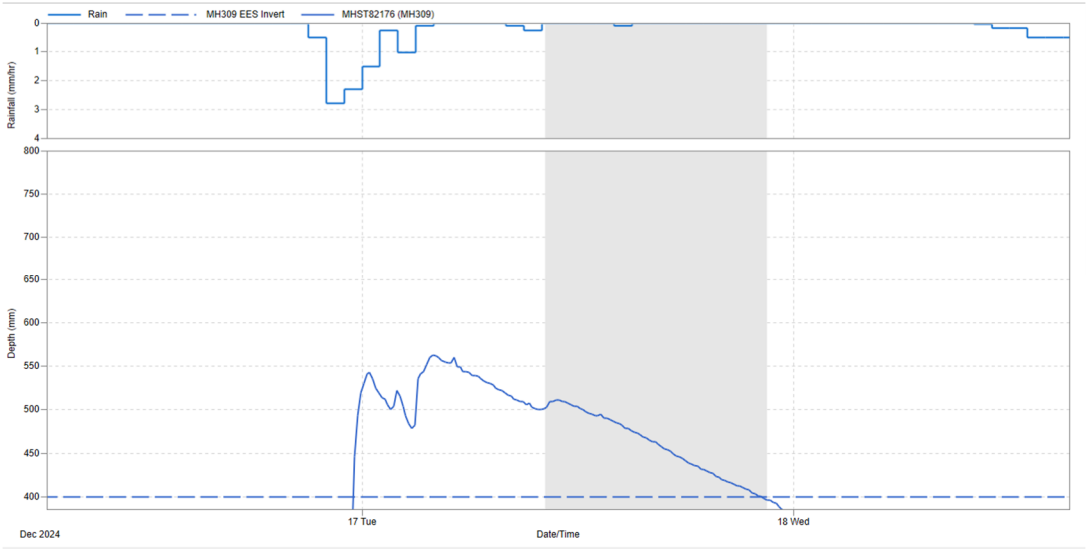

3.7.4 Operation and Maintenance Activities - EES

Operation and Maintenance (O&M) activities are essential to ensure the long-term functionality and performance of a newly installed EES. As for the systems operational in Quinn's Pointe Subdivisions, the proposed EES will become part of the city's wastewater collection system.

A **Draft** Operation and Maintenance Manual (OMM) was prepared and included in Appendix L. The Manual is intended in assisting the city with typical procedures to reduce the risk of blockages and other events which could trigger costly emergency interventions and would extend the system's service life (refer to Appendix L). The **Draft** Manual will be submitted as

part of detailed design of Stage 5 and Stage 6. It is also the intent to include the **Manual** in an Appendix in the upcoming 2026 EES Monitoring Report and shared to the group which attended the June 17, 2025 meeting to discuss EES monitoring.

3.8 Consolidated Linear Infrastructure Environmental Compliance Approval

In 2022, the Ministry of the Environment, Conservation and Parks (MECP) launched a new approval process with the goal of modernizing the approach to authorize construction of linear infrastructure and stormwater management facilities. The intent of the framework was to reduce efforts on both the Ministry and with Municipalities by setting up a consistent set of conditions to improve environmental protection. By doing so, the old system which consisted of the issuance of individual Environmental Compliance Approval (ECA) would be replaced by a system that relies on pre-authorization of works with conditions. The new system adopted by MECP is referred to as the Consolidated Linear Infrastructure Environmental Compliance Approval (CLI-ECA).

On December 10, 2025, and January 27, 2026, the City of Ottawa received their CLI-ECA for storm and sanitary, respectively. The transition period for the storm CLI-ECA is identified as December 26, 2026. However, the transition does not apply to the S1 Area as the infrastructure is proposed and will be constructed in 2027. The said infrastructure will need to be designed in accordance with MECP's document entitled "Design Criteria for Sanitary Sewers, Storm Sewers and Forcemains for Alterations Authorized under an Environmental Compliance Approval (May 31, 2023)".

3.9 Evaluation of Servicing Strategies

3.9.1 General

A stormwater management strategy has been developed on a functional level basis based on the following constraints/targets:

- Residual capacities of existing storm outlet sewers (Section 3.2).
- Off-site post-development peak flow and runoff volume discharging to MTO's Borrisokane Road open ditch system will be limited to those of the pre-development condition.
- Off-site post-development peak flow and runoff volume discharging to the Barnsdale Road open ditch system will be limited to those of the pre-development condition.
- Off-site post-development peak flow and runoff volume discharging to the Thomas Baxter Municipal Drain, when the above contributions are accounted and will be limited to those of the pre-development condition.
- Runoff volume control target hierarchy, as presented in the screening process of the CLI-ECA, as follows:
    - Hierarchy Priority No. 1: LID Infiltration/retention
    - Hierarchy Priority No. 2: LID Filtration
    - Hierarchy Priority No. 3: Conventional treatment

Similar to the 2018 BSUEA MSS, the implementation of LID infiltration/retention alternatives to maintain pre-development water balance appears to be feasible based on actual measured data compiled by Paterson (Section 2.5.3). However, infiltration LIDs will only be possible in areas not impacted by constraints listed in Table A2.

Sections 3.10 and 3.11 summarize the screening process carried out that identified both preferred alternatives (infiltration-type and filtration LID), respectively within the S1 Area.

3.10 Screening Process - Infiltration-Type Servicing Strategies

3.10.1 General

In light of the runoff volume control hierarchy noted above, infiltration measures are to be maximized to the full extent while recognizing the constraints in Table A2 of the CLI-ECA before contemplating filtration servicing solutions. The following sub-sections summarize the screening process used to develop the preferred infiltration servicing strategies.

3.10.2 BSUEA MSS (2018)

Several infiltration-type measures were reviewed and evaluated in 2016 as part of a screening process undertaken as part of the 2018 BSUEA MSS. Infiltration measures reviewed included the following:

- Roof leader to soak away pits
- Perched rear yard CB with rear yard perforated system
- Previous catch basin with sand filter
- Etobicoke Exfiltration System (EES)
- Sub-surface infiltration trench.

From the screening of the above-noted practices, the 2018 BSUEA MSS determined that measures located within private properties were to be disregarded. It was concluded that the preferred infiltration LID solutions would consist of the following measures (refer to Appendix E of the 2018 BSUEA MSS, in Appendix C):

- **Etobicoke Exfiltration System (EES):** An EES along local roads, sized to capture the 22 mm event, based on measured groundwater levels would be sufficient to maintain the pre-development infiltration condition.
- **Other Infiltration Practice:** Infiltration of rooftop flows, as a source of clean water, should be adopted on all Site Plans, including school, library, Park & Ride, etc. Infiltration should be conducted using sub-surface LID measures such as infiltration galleries, cistern, etc. that would be sized to capture and infiltrate the 22 mm event.

Several Memoranda were prepared in support of the above-noted recommended infiltration strategy being the EES along local roads (refer to Appendix C for the 2018 BSUEA MSS, with Memoranda included in Appendix E of that MSS).

As part of the 2018 BSUEA MSS, it was concluded that the implementation of an EES sized for a 22 mm capture along local roads was equivalent, on average, to 150 m^3/ha which surpasses

the MECP's SWMPDM (20023). Additional details with respect to the achievement of the quality criterion, based on the 2023 SWMPDM, is provided in Section 3.11.6.2 and Section 3.11.6.3.

3.10.3 2026 Screening Process

The infiltration LID solutions recommended as part of the 2018 BSUEA MSS were extended to the S1 Area, when feasible, in areas not impacted by the constraints identified in Table A2.

Given the runoff volume target hierarchy, infiltration servicing solutions are set as highest priority and shall be developed to the maximum extent possible, as per the CLI-ECA. However, the use of infiltration LID solutions is to account for the constraints listed in Table A2, were deemed applicable. Constraints, which preclude the use of infiltration-type LID solutions, include the following:

- ✓ Areas of high groundwater levels - Constraint (b)
- ✓ High Risk Activities – Constraint (e)
- ✓ Source protection Restrictions – Constraint (f)

The above-noted constraints have been accounted for in the selection of areas where infiltration-type servicing solutions can be implemented.

3.10.3.1 Groundwater Mounding Risk

The new SDG (Appendix 10) requires that groundwater mounding calculations be supplied when the separation between the bottom of the EES and seasonal high groundwater is less than 1 m.

The routing of both storm sewer and EES was revisited from the initial version of the MSS (October 2025) with the minimum 1.0 m criterion set as a firm constraint. Based on the revised storm sewer and EES routing, all the proposed EES meet the minimum 1 m separation.

A Figure was prepared that displays the separation for all proposed EES reaches with the high seasonal groundwater level as measured by Paterson. This Figure, included in Appendix G, showed that the 1 m criterion is met.

3.10.3.2 Evaluation of Infiltration LID Servicing Alternatives

The feasibility of infiltration solutions was assessed using several criteria including high-risk activities, land use, areas of high groundwater. Based on this review, the S1 Area was broken down in several areas. For each of these areas, evaluation criteria table was developed based on a color-coding system where:

- Highly positive is shown in green
- Highly Negative is shown in red

Table 6 below provides a summary of the evaluation impact of infiltration LID alternatives being proposed with the design capture as they relate to individual growth areas located below (refer to Figure 9 for Location of Areas).

Table 6: Infiltration LID Evaluation Impact

Area No.	Area Type	Infiltration-Type LID	Impact Level	Relative Impact	Design Capture
1A & 1B	Local Roads > 1 m separation to groundwater	EES	Strong Positive Impact	Preferred	22 mm
1C	Local Roads < 1 m separation to groundwater	EES	Negative Impact	Least Preferred Constraint (b)	N/A
2	Collector Roads	EES	Negative Impact	Least Preferred Constraints (e) and (f)	N/A
3A & 3B	High Risk Areas Industrial Lands	Rooftop Infiltration (only)	Strong Positive Impact	Preferred	22 mm
3A & 3B	High Risk Areas Industrial Lands	EES along Roads or Parking	Negative Impact	Least Preferable Constraints (e) and (f)	N/A
4	Park Land[1]	Sub-surface Infiltration	Strong positive Impact	Preferred	22 mm
Area 5A & 5B	Woodlots[2]	N/A	N/A	N/A	N/A

Notes: [1] Servicing within the Park to be developed to maintain: i) pre-development infiltration levels by means of sub-surface methods and ii) pre-development peak flows and runoff volumes. Accordingly, water budget was simulated using the same parameters.
[2] Pre-development and post-development water budget was carried out using same parameters as the ecological function will remain.

Based on the above Infiltration LID evaluation impact table, the following conclusions are drawn:

- An EES system is to be implemented to capture and infiltrate the 22 mm event in Areas 1A & 1B when separation of 1 m exists between the bottom of granular and seasonal high groundwater table.
- Within the Industrial lands (Areas 3A and 3B), infiltration of rooftop flows is to be implemented using a sub-surface system to capture and infiltrate the 22 mm event.
- Filtration LID solutions to be developed to the maximum extent for Areas 1C & 2.
- Given that Areas 3A and 3B when developed, will include on-site stormwater management controls which will meet the applicable quality control criterion at the time of approval, filtration-type solution will not be accounted for these areas.

3.11 Screening Process - Filtration-Type Servicing Alternatives

3.11.1 Design Constraints

Filtration LID solutions were developed to the maximum extent within the S1 Area, while recognizing that an EES is only being proposed in Area 1A and Area 1B as shown in Figure 9. As per the CLI-ECA, filtration LID solutions must also be reviewed the maximum extent.

Several filtration LID solutions were reviewed to the maximum extent within Area 1C and Area 2. In addition, the screening of filtration-type LID alternatives was completed while accounting with Constraint (n) - Economic Considerations. As a result, the selection of the filtration LID alternative also accounted for economic considerations when capital, lifecycle and/or operation and maintenance costs are taken into consideration.

3.11.2 Filtration-Type LID Solutions

Five (5) servicing alternatives were developed and screened using a set of criteria identified as having either major or minor influence on the evaluation. The filtration-type LID solutions consist of the following alternatives:

Alternative 1: Do Nothing
Alternative 2: Subdivision Level LIDs (Bio-Retention Bump-Outs and Porous Sidewalks)
Alternative 3: Stand Alone Manufactured Treatment Device (MTD)
Alternative 4: Pre-Treatment MTD + Underground Filtration Chambers
Alternative 5: Pre-Treatment MTD + Infiltration Dry Pond

A short description for each of the above alternatives is provided in the following sub-sections.

3.11.2.1 Alternative 1: Do Nothing

Alternative 1 is the standard “Do Nothing” option. Under this alternative, no servicing measure would be adopted. Accordingly, this alternative is considered as the baseline against the impacts of other alternatives when it is compared. This alternative does not address the identified issues and has only been carried forward as the baseline alternative for evaluation.

3.11.2.2 Alternative 2: Bump-Out Retention and Porous Sidewalks

This alternative consists of subdivision-level LID measures implemented along municipally owned ROWs with bump-out bioretention cells and porous sidewalks.

Bump-out bioretention cells: These are small, landscaped stormwater management features constructed along ROWs with engineered soil media, underdrains (where required), and vegetation tolerant of both dry and inundated conditions. Runoff enters the cell through curb cuts or inlets, allowing sediments and pollutants to settle and be filtered through the soil profile. Treated water would then be conveyed to the storm system via an underdrain. Bump-outs are typically integrated as a traffic calming measure along the ROW.

Given that they would be introduced in areas of high groundwater table (Area 1C) and/or along collector roads (Area 2), they would be designed to capture the 22 mm event and filer roadway and sidewalk runoff before being discharged as treated runoff back into the storm sewer system.

By intercepting runoff at the source, these systems improve water quality, reduce peak flows, and support LID filtration objectives.

In addition to stormwater benefits, roadway bump-out bioretention cells provide urban design and transportation advantages. They visually narrow the roadway, which can help calm traffic, shorten pedestrian crossing distances, and enhance streetscape aesthetics. When properly designed and maintained, these systems contribute to greener, safer, and more resilient urban environments while making efficient use of limited right-of-way.

Porous Sidewalks: would be implemented along the ROWs and allow runoff to flow along its surface where it would infiltrate through its surface and underlying soil or into a filter media. Given that porous sidewalks would be used in either the high groundwater area or along collector roads, this system would be underlain with a filter media. In addition to providing treatment via filtration, it would also provide the advantage of reducing peak flows discharging into the storm sewers.

3.11.2.3 Alternative 3: Stand Alone Manufactured Treatment Device

Another servicing alternative that would achieve the filtration requirements of the CLI-ECA would consist of implementing a single or multiple Manufactured Treatment Device(s) (MTD) at the downstream end of the storm sewer systems to meet the 80% TSS removal on its own. Given the size of the sewershed, multiple MTDs would be sized to meet the ISO 14034 Environmental Technology Verification (ETV) protocol as per Section 5.2.5 of the CLI-ECA.

To meet the ETV protocol, the treatment process of the MTD is based on filtration as opposed to dynamic settling of particulates. Commonly used MTD meeting the ETV protocol, include the Jellyfish® or Stormfilter®, distributed by Imbrium and Contech, respectively which could provide filtration of large sewersheds.

Filtration end-of-pipe MTDs are more onerous than regular oil grit separators (OGS), which no longer complies with the new MECP framework. The capital cost of a filtration type MTD is significantly more than a standard OGS as these are sized on fine particles as opposed to ETV particle size.

In addition to a higher capital cost, the operation and maintenance (O&M) costs for multiple end-of-pipe MTDs is more onerous and labor intensive when compared to the traditional OGS as individual filters would require to be rinsed and cleaned and be replaced on a bi-annual basis. These aggregate costs are in line with Constraint (n) of Table A2 (Economic Considerations).

3.11.2.4 Alternative 4: Pre-Treatment MTD combined with Filtration LID System

This storm servicing alternative would be implemented as a treatment train system, with pre-treatment provided by a manufactured treatment device (MTD) designed to capture the coarsest sediment fraction (TSS removal of ±35-40%). Effective pre-treatment is critical to protect the filtration chambers and underlying native soils from premature clogging and increased long-term maintenance requirements.

The MTD would be sized to achieve removal of coarse-to-medium sediment particles (±35-40% TSS). Following pre-treatment, runoff from the 22 mm event would be conveyed downstream

into a flow splitter manhole where flows up to ±1.0 m^3/s would be directed into the underground system consisting of a series of Stormtech chambers, or approved equivalent, while flows in excess would be directed towards the downstream dry pond.

Runoff conveyed to the underground chambers would be spread among the eight (8) isolator rows for TSS removal, where it would be directed downward by gravity through the ADS's proprietary underlying non-woven geotextile. The separation and filtration properties of the geotextile would provide the required 80% TSS removal of total suspended solids (TSS).

3.11.2.5 Alternative 5: Pre-Treatment MTD combined with Filtration Dry Pond

Similar to Alternative 4, this servicing alternative would be implemented as a treatment train system, with pre-treatment provided by a manufactured treatment device (MTD) designed to capture the coarsest sediment fraction (ETV particle size) followed by a filtration dry pond. Effective pre-treatment is critical to protect the downstream filtration dry pond from premature clogging and increased long-term maintenance requirements.

The proposed filtration dry pond would function as a passive stormwater quality control measure that relies on bioretention soil media as the primary treatment mechanism. Runoff entering the facility would be temporarily stored within the pond and treated through vertical filtration as it percolates through the engineered bioretention soil layer, which is designed to promote sedimentation, filtration, and adsorption of pollutants. Beneath the soil media, an underdrain system installed within a clear stone envelope would collect the filtered runoff and convey it to the sub-drain system. The clear stone layer provides structural support, maintains hydraulic conductivity, and facilitates uniform drainage, while the perforated subdrains ensure positive drainage under low-permeability soil conditions and limit prolonged ponding. Together, the pre-treatment MTD and bioretention media and underdrain system provide effective removal of TSS (80% removal) while maintaining reliable long-term performance and manageable maintenance requirements.

3.11.3 Evaluation of Filtration LID Servicing Alternatives

The five (5) filtration-type LID alternatives were evaluated using a similar screening process adopted in Section 3.10.3.1. The evaluation of the five (5) servicing solutions was based on a similar color-coding system which was applied to each criterion to represent its relative level of impact as follows:

- Green: Most Favorable and Least Disruptive Impact
- Yellow: Moderately Favorable and Moderately Disruptive Impact
- Orange: Least Favorable and Most Disruptive Impact

The relative impact of each criterion across the five (5) alternatives was assessed with a different weight placed on the following key considerations:

i. Fish Habitat Protection: 5 Points
ii. Achievement of the CLI-ECA: 5 Points
iii. Impact on Esker: 5 Points
iv. Aesthetics/Safety: 3 Points
v. Construction Considerations: 3 Points

vi.	Runoff Control Volume:	5 Points
vii.	Operational Requirements:	5 Points
viii.	Capital Cost Consideration:	5 Points
ix.	Lifecycle Consideration:	5 points
x.	O&M Cost Considerations:	5 Points

The alternative demonstrating the lowest overall negative impact and/or the strongest positive performance across these criteria was identified as the preferred solution.

3.11.4 Recommended Filtration-Type LID Solution

The screening of the above-noted five (5) alternatives has been summarized in an Evaluation Matrix in Table 7 (below). As previously noted, an emphasis was made on specific indicators by assigning a more important score of 5 and smaller emphasis on other criteria by assigning a score of 3.

The following conclusions are drawn from the screening process summarized in Table 7:

- **Alternative 1** (Do nothing) approach was deemed the most disruptive solution at a score of -50 and immediately dismissed.
- **Alternative 2** met the filtration objective; however, its score of -14 is indicative of being disruptive mainly due to the potential size of features, lifecycle and operation and maintenance costs (Constraint (n)) and disregarded from any further review/analysis.
- **Alternative 3** met the filtration objective; however, its low score of 1 is indicative of being moderately disruptive due to its substantial operation and maintenance costs (Constraint (n)) and also disregarded from any further review/analysis.
- **Alternative 4** met the filtration objective using the treatment train approach. The alternative shows a score of 21 which is indicative of a neutral rating. Its most adverse criteria lie with lifecycle costs which implicates the replacement of the geotextile fabric and replacement of all chambers. The timing of this costly replacement is unknown as this system appears to be relatively recent on municipally owned projects (less than 5 years old). The unknow lifecycle cost has reduced its rating when compared to other methods (Constraint (n)).
- **Alternative 5** also met the filtration objective using the treatment train approach. The alternative shows the highest score of all alternatives at 36 which is indicative of being the preferred solution. Similar systems have been implemented in Ottawa, and its long-term operation and maintenance requirements would appear to be less than Alternative 4.

Based on the above screening, Alternative 4 and Alternative 5 have scored the highest, with Alternative 5 shown as the preferred solution.

Table 7: Evaluation Matrix (Filtration Alternatives)

MAJOR CRITERIA	MINOR CRITERIA	ALTERNATIVE 1	ALTERNATIVE 2 SUBDIVISION LEVEL LIDS	ALTERNATIVE 3 STANDALONE MTD	ALTERNATIVE 4 MTD UNIT + UNDERGROUND FILTRATION SYSTEM	ALTERNATIVE 5 MTD UNIT + FILTRATION DRY POND
DESIGN COMPONENTS		**Do Nothing**	**ROW Bio-Retention Bump-Outs + Porous Sidewalks**	**Stand Alone MTD (ETV Sized)**	**MTD unit as Pre-Treatment Underground ADS Filtration Chambers**	**MTD unit as Pre-Treatment + Filtration Dry Pond including**: Filter Media + Perforated drain/clear stone + Filtration Berm
NATURAL ENVIRONMENT	**Fish Habitat (Jock River via Corrigan Pond)** **5 Points**	• Highly Disruptive **-5 Points**	• Improves water quality and enhances fish habitat protection **5 Points**	• Improves water quality and enhances fish habitat protection **5 Points**	• Improves water quality and enhances fish habitat protection **5 Points**	• Improves water quality and enhances fish habitat protection **5 Points**
TECHNICAL/ SOCIAL/ OPERATIONAL	**CLI-ECA Objectives: Effectiveness of Alternative** **5 Points**	• Not Achieved **-5 Points**	• Bio-retention bump-out sized to capture and provide filtration of 4hr 22 mm • Porous sidewalk to accommodate runoff from the boulevard for the 4hr 22mm Measures in tandem to be sized to meet the filtration requirement of the CLI-ECA **5 Points**	• MTD (single of multiple units) sized to achieve an 80% TSS removal (ETV particle) Servicing alternative would meet the filtration requirement of the CLI-ECA achieved **5 Points**	• MTD unit sized as pre-treatment only (35-40%) based on ETV particle size • Underground ADS filtration chambers sized to achieve an 80% TSS removal Measures in tandem sized to meet the filtration requirement of the CLI-ECA **5 Points**	• MTD Unit sized as pre-treatment (35-40%) based on ETV particle size • Infiltration Dry Pond to incorporate filtration components Measures in tandem sized to meet the filtration requirement of the CLI-ECA **5 Points**
	Impact on Esker **5 Points**	• Highly Disruptive **-5 Points**	• No Adverse impact – Filtration is used **5 Points**	• No Adverse impact – Filtration is used **5 Points**	• No Adverse impact – Filtration is used **5 Points**	• No Adverse impact – Filtration is used **5 Points**
	Aesthetics and/or Safety **3 Points**	• Highly Disruptive **-3 Points**	• Bio-retention bump-out can adversely impact the aesthetics, if vegetation is overgrown • Safety concerns can exist with overgrown vegetation **-3 Points**	• MTD is a sub-surface feature not impacting aesthetics nor safety **3 Points**	• MTD is a sub-surface feature not impacting aesthetics nor safety • ADS filtration system is a sub-surface system not impacting aesthetics nor safety **3 Points**	• MTD is a sub-surface feature not impacting aesthetics nor safety • Infiltration dry pond offering no safety concerns as fully contained within Block 61 **3 Points**
	Construction Considerations **3 Points**	• Highly Disruptive **-3 Points**	• Reduce on-street parking • Additional constraints with buried utilities • Limits future utility upgrades • Vegetation impacted by salts **-3 Points**	• MTD and Chambers buried along ROW and SWM Block • No impact on utilities **3 Points**	• MTD and Chambers buried along ROW and SWM Block • No impact on utilities **3 Points**	• MTD and Dry Pond located along ROW and SWM Block, respectively • No impact on utilities **3 Points**
	Runoff Control Volume (22 mm) **5 points**	• Highly Disruptive **-5 Points**	• Disruptive • Difficult to Achieve Solely at Roadway Sags **-3 Points**	• Can be achieved at a Higher Cost **0 Points**	• Can be achieved **5 Points**	• Can be achieved **5 Points**

3.11.5 Functional-Level Design Information

Conceptual level information is provided below for Alternative 4 while functional level information is presented for Alternative 5 (refer to Appendix F for details).

Alternative 4 - Pre-Treatment Manufactured Device with Filtration Chambers

High-level information is provided for Alternative 4, the option that scored the second highest at 21 as part of the screening process (Table 7) but not recommended for a more detailed review.

Alternative 4 was developed based on a treatment train servicing approach where an upstream Manufactured Treatment Device (MTD) has been conceptually sized for pre-treatment (35-40% TSS removal) followed by a commercially distributed sub-surface filtration system consisting of a series of underground chambers designed as isolator rows along with a bypass manhole. This system in tandem was sized to capture and provide filtration of the 22 mm design event.

High-level information was supplied at the onset by ADS; however, the information has not been revised to account for the latest changes in the hydraulic profiles which would result by using lower rise chambers and having a larger footprint which would provide increased filtration. Given that Alternative 4 is not the preferred option, the high-level information provided was deemed sufficient for the purpose of evaluating this servicing option. The information consists of the following:

- By-pass manhole (flow splitter) directing the 22 mm event to the filtration system while excess flows would by-pass the filtration system and be conveyed to the downstream dry pond.
- Pre-treatment MTD - Defender Model (FD-8HC) - ETV particle size.
- Stormtech Underground System consisting of:
  - Eight (8) Isolator rows (MC7200 chambers)
  - 88 MC7200 Chambers & 16 MC7200 End Caps
  - Sub-drain system including a by-pass manhole (flow splitter)
  - Clear stone above and between chambers
- The volume requirements of the system (±795 m^3) include the clear stone surrounding the chambers (void ratio of 0.40). Volumetric requirements based on the filtration capacity of the geotextile (4.1 gpm/ft^2) and the runoff hydrograph from the 22 mm storm.

High-level information from ADS is contained in Appendix F, including:

- Data on the proposed MTD (Defender FD-8HC)
- High-level concept of the Stormtech filtration chambers
- Manufacturer’s Inspection and Monitoring requirements (page 4/5) of the attachment

The performance of the above-noted system is as follows:

- 37% TSS removal is provided by the MTD (Defender FD-8HC)
- 80% TSS removal by 8 Isolator rows
- 87 TSS removal combined between the MTD & filtration system
- 98.8% of total volume treated

The above-noted performance data is also contained in Appendix F.

Alternative 5 - Pre-Treatment Manufactured Device with Filtration Dry Pond

As per the screening process and Evaluation Table (Table 7), Alternative 5 scored the highest at 36. Consequently, it is recommended as the preferred filtration LID Solution. Functional level information is provided below for Alternative 5 (refer to Appendix F and Appendix K for Drawings).

Alternative 5 was developed based on a treatment train approach where an upstream MTD has been conceptually sized for pre-treatment followed by a filtration dry pond. Both MTD and filtration dry pond was sized to capture, pre-treat and provide filtration of the 22 event prior in being released into the adjacent dry pond.

Alternative 5 consists of the following components:

- Defender Model FD-8HC (ETV particle size)
- Flow-splitter manhole forcing the 22 mm to the filtration dry pond while flows in excess, would by-pass the filtration dry pond and would be conveyed to the downstream dry pond.

The simulated filtration rate of the facility was assumed to be consistent with the measured unfactored infiltration rates reported by Paterson in their Existing Conditions Report at BH2-22, the closest borehole, as the amended soil's performance would be similar.

An average infiltration rate of 126 mm/hr was, therefore, calculated based on two (2) measurements of unfactored infiltration rates at BH2-22. A 2.5 safety factor was then applied to the average unfactored infiltration rate of 126 /mm/hr for an overall effective assumed filtration rate of 50.4 mm/hr. The assumed filtration rate of 50.4 mm/hr is consistent with the amended soil filtration rate of 50 mm/hr recommended by Sustainable Technology Evaluation Program (STEP).

Configuration of Filtration Dry Pond consisting of:

- Operating Levels: 100.10m – 100.80 m
- 3:1 side slope
- Filtration rate: 50.4 mm/hr
- Maximum Ponding Depth prior to Spill: 700 mm
- Spillway (15 m wide): 100.80 m
- Footprint at elevation 100.10 m: 1,822 m^2
- Surface Area at Spill of 100.80 m: 2,235 m^2
- Volume of Filtration Dry Pond: 1,418 m^3
- Hydro-seeded footprint & side slopes
- Amended soil (bio-retention soil media) 500-700 mm filter media
- Choker Layer 100 mm
- Clear stone 300-350 mm
- subdrains (spurs & header) 150 mm and 200 mm
- Inspection/clean-out ports

The proposed servicing within Block 61 along with pre-treatment is shown on Drawing MST (Appendix K) with information included in Appendix F. The above-noted configuration of the filtration pond as well as the filtration rate will be reviewed at detailed design.

3.11.6 Water Quality Control Assessment - Infiltration/Filtration Practices

3.11.6.1 General

An 80% TSS removal has been historically used for any development tributary to the Jock River, Rideau River and/or Thomas Baxter Municipal Drain (Mud Creek). Storage volume requirements for different types of SWM practices to achieve an 80% TSS removal are identified in Table 3.2 of MECP's publication entitled "Stormwater Management Planning and Design Manual, March 2003".

Quality control requirements for municipal works have since evolved with the implementation of MECP's framework which is based on pre-authorized works defined in the CLI-ECA, particularly those described in Appendix A.

Section 3.11.5 identified the preferred filtration alternative as Alternative 5. It consists of a pre-treatment MTD combined to a filtration dry pond. Given that this Addendum extended the analyses and conclusions from the 2018 BSUEA MSS, the design capture of the 22 mm event was maintained. Hence, the capture of the 22 mm event was extended to the sizing of the filtration solution given that it also relies on infiltration/filtration through a bio-retention media.

As a parallel verification, the proposed infiltration and filtration LIDs is being reviewed against Table 3.2 to ensure that it meets its recommendations. Sub-sections 3.11.6.2 and 3.11.6.3 summarize the verification against Table 3.2.

3.11.6.2 Infiltration Practices

An EES is proposed within two (2) residential blocks located north of Cappamore Drive, and east and west of Elevation Road. These Blocks have been identified as Area 1A and Area 1B on Figure 9.

Based on the average imperviousness of ±64% for each residential areas serviced by an EES, a water quality storage of ±33 m³/ha was calculated to be necessary to achieve 80% TSS removal based on interpolation between imperviousness of 55% (25 m^3/ha) and 70% (35 m^3/ha) for an infiltration SWM Practice. Based on an EES along local roads sized for the 22 mm event (per 2018 BSUEA MSS), the storage volume provided is equivalent, on average, to ±150 m³/ha. Therefore, the proposed EES along local roads (±150 m^3/ha) by far exceeds the infiltration requirements of 33 m^3/ha, the enhanced level of protection per Table 3.2 of the SWMPDM. Consequently, no further downstream water quality controls are necessary for Areas 1A and 1B apart from the EES as it meets Table 3.2 and the CLI-ECA.

3.11.6.3 Filtration-Type Practices

The screening process presented in Section 3.11.2 to 3.11.5 concluded that the preferred filtration LID solution consisted of Alternative 5. It includes a pre-treatment MTD combined to a filtration dry pond. As noted, the pre-treatment MTD under Alternative 4 will provide a 37% TSS removal based on ETV particle size.

The filtration dry pond was sized to capture and filtrate the 22 mm event using a bio-retention soil media with an underlain sub-drain system and clear stone envelope. Although the effluent is not infiltrated, the filtration mechanism proposed remains equivalent to infiltration; however, the filtered runoff will be conveyed in the dry pond portion of Block 61 for quantity control.

The filtration dry pond described in Section 3.11.5 would service Area 1C (high groundwater table) along with Area 2 consisting of the three (3) collector roads due to roadway salts. When both Area 1C and Area 2 are combined, an overall area of ±20.4 ha and average imperviousness of ±67% was calculated. Given that the proposed filtration dry pond operates as an infiltration SWM practice with an underlain sub-drain system, a storage volume of 34 m^3/ha was estimated by means of interpolation between imperviousness of 55% (25 m^3/ha) and 70% (35 m^3/ha) for this SWM practice. Based on an area of ±20.4 ha and the storage volume of 34 m^3/ha, the filtration dry pond should be sized with ±700 m^3. As shown in Section 3.11.5, the volume provided is 1,629 m^3 thereby exceeding the volume of Table 3.2. Consequently, the filtration dry pond is found to meet both Table 3.2 and CLI-ECA (Appendix A).

The proposed servicing of Block 61 along with pre-treatment is shown on Drawings K1 and MST is well as on Drawing POND and D2 in Appendix K.

3.12 Storm and Stormwater Servicing Assumptions and Methodology

The design and evaluation of the proposed storm servicing strategy was undertaken with the PCSWMM platform. Several design parameters and assumptions have been made to support both minor and major system designs as described in the sub-sections that follow.

3.12.1 Runoff Coefficient

Surface runoff is generated when precipitation exceeds the infiltration capacity of the landscaped surface and/or the initial abstraction of hard surfaces. To assess runoff rates from the various surfaces, hydrological parameters representing different drainage characteristics were calculated. The type of land cover and associated hydrological parameters are based on area weighting of each catchment's imperviousness using the various breakdown shown in Table 8.

Table 8: Land Cover Drainage Parameters

Land Cover	Impervious (%)	Runoff Coefficient	Draining to Pervious (%)
Collector Roads	71	0.70	0
Local Roads	64	0.65	0
Parks	36	0.45	100
Woodlots	0	0.20	100
Single Family Residential	64	0.65	70
Townhouse Residential	64	0.70	70
Back-to-Back Residential	71	0.70	70
Industrial Lands	86	0.8	0

Based on the guidance of the SDG, Runoff Coefficients (C-Factors) associated with the various types of residential usages were based on actual impervious areas for the adjoining Quinn's Pointe subdivision. Similar housing product will be proposed as part of the S1 Area.

3.12.2 Storm Sewer Sizing

Preliminary sizing of storm sewers was carried out based on the design criteria listed in Section 3.5.3 for the proposed road patterns shown on the Concept Plan (Appendix D). The storm servicing strategy was also developed while respecting the filtration and infiltration servicing solutions presented in Section 3.10 (infiltration) and filtration (Section 3.11.2). As such, the storm sewer strategy was developed with two (2) independent storm systems; one that collects and convey runoff from areas serviced by an EES and a second independent storm sewer system collecting runoff from collector roads and areas of high groundwater.

This functional level exercise is intended to demonstrate the feasibility of the overall storm servicing strategy. The preliminary storm sewer layout and associated drainage areas are shown in the following drawings (Appendix K):

- KS1: Key Servicing Plan
- MG1: Master Grading Plan
- MST: Master Storm

Based on the above Drawings, storm sewer design sheets have been prepared and included in Appendix G. The traditional storm sewers along the various road types have been sized in accordance with the level of service identified in Section 3.5.3, being 1:2 year and 1:5-year capture for local and collector roads, respectively.

3.12.3 Roadway Sag Storage

The Master Grading Plan (Drawing MG1 in Appendix K) was developed to provide a route to safely convey major overland flow while minimizing earth works. To fulfill these objectives, grading along the major overland system will be carried out following a saw-tooth profile with low points introduced along the major overland system. Since detailed design will dictate the location and extent of the roadway sag depths, modelling was carried out assuming an on-site storage of 70 m^3/ha which reflects the storage achieved in the Quinn's Pointe Subdivisions. Roadways with flatter slopes will generate greater storage capacity, while those that are steeper will have limited storage capacity.

The design of the major overland system will allow runoff to be stored in the roadway depressions prior to its capture by the catch basins and inlet control devices (ICD). During infrequent events, runoff exceeding the rate of capture of the minor system and roadway sag storage will cascade along the major overland system.

3.12.4 Dual Drainage Modelling – Assumption and Parameters

The PCSWMM software platform was used to simulate hydrology with the given land use and corresponding imperviousness shown in Table 8Table 8 as well as confirming the preliminary minor and major systems and the assessment of the post-development water budget by modelling the infiltration opportunities documented in Section 3.10.3.

The software used combines the EPA SWMM engine within a powerful GIS environment. The PCSWMM dual drainage model will provide preliminary confirmation of the overland flow depths along the local/collector roads, feasibility of the proposed sewer sizing in terms of hydraulic grade line (HGL) elevations, confirm block sizing of Block 61, the assessment of the proposed infiltration measures and the off-site peak flow discharges. Model inputs and results are contained in Appendix L.

The dual drainage analysis uses a dynamic simulation to calculate the hydrology and hydraulics of the major and minor systems. The model has been developed based on the following:

- The Chicago and SCS design storms derived from the Ottawa Intensity-Duration-Frequency (IDF) statistics which were applied across catchments with characteristics area weighted imperviousness.
- Sag storage of 70 m³/ha applied as a storage node for each residential sub-catchment.
- Both Industrial Blocks have been modelled assuming sufficient storage to self-contain their own runoff up to and including the 1:100-year storm in accordance with the SDG for the given land usage.
- A 1:2 year and 1:5-year design capture for the local and collector roads, respectively.
- Exit losses are applied at the downstream end of each section of sewer based on the SDG.
- Storm Sewers have a minimum cover of 1.3 meters below the proposed centre line grades shown on Drawing MG1. With this minimum freeboard to the HGL elevation, underside of footings (USFs) will meet the prescribed minimum freeboard of 300 mm.
- Several unfactored infiltration rates were used to represent the soil characteristics in areas where an EES is being contemplated. Paterson's unfactored infiltration rates were reduced by 2.5 to account for a safety factor. Simulated unfactored infiltration rates are presented in Section 3.13.1.1.
- The storage and filtration were simulated as a storage node along the minor system. This configuration within residential areas has proven to demonstrate the capture of the 22 mm storm and maintain pre-development infiltration conditions (refer to the BSUEA MSS, Appendix C).
- Roof areas in the Industrial Lands were assumed to reflect 30% of the overall area. The same assumption was used as part of the BSUEA MSS for any of the ICI Blocks. It was assumed that infiltration measures would be implemented to capture and infiltrate by means of sub-surface systems the 22 mm storm.

3.13 Simulation Results

Several types of simulations have been carried out to assess the performance of proposed servicing, including the water budget, sizing of linear infrastructure, major overland flow route, as well as confirming sizing of features in Block 61. Th following sub-sections provides these assessments.

3.13.1 Post-Development Water Budget

The existing condition water budget revealed that existing infiltration across the overall S1 Area accounted for 34% of the total annual precipitation based on long-term simulations (refer to Section 3.6 and ECR in Appendix B).

A similar analysis was carried out to assess the post-development water budget while accounting for constraints within the S1 Area as well as the opportunities within the S1 Area to incorporate an EES. As noted under Section 3.10.3, all EES being proposed provide the minimum 1 m separation between the seasonal high groundwater and the bottom of granular (refer to Appendix G for Figure displaying the separation between EES and groundwater). All EES lengths have been accounted for as part of the water budget and during detailed design best efforts will be made to utilize all EES lengths for the purpose of achieving the pre-development water budget. This is achieved by placing the plugs for the first reach at the downstream end. The sub-sections that follow provides the approach and assumptions made as part of the post-development water budget.

3.13.1.1 Simulated Infiltration Rates

The Existing Conditions Hydrogeological Report prepared by Paterson documented the hydrogeological condition within the S1 Area (refer to Section 2.5.3). As part of this undertaking, Table 3 documented the unfactored infiltration rates measured in the field.

The information summarized in Paterson's Table 3 along with other historical unfactored infiltration rate measurements were used to simulate the performance of the EES in various sub-areas (refer to Figure 9 for details). As shown in the table below, the largest area, namely Area 1A, was broken down into three (3) smaller areas; the northern part which consists of the area north of Moyard Drive, with two (2) smaller areas south of Moyard Drive consisting of an area to the west and one to the east.

It should be noted that the unfactored infiltration rates noted in Paterson's Table 3 were derived based on the Site Evaluation and Soil Testing Protocol (Appendix C) of the CVC/TRCA LID Manual. The simulated unfactored infiltration rates shown in Table 9 below, includes the 2.5 safety factor.

Table 9: Simulated Unfactored Infiltration Rates

Area No.	Borehole No	Average Unfactored Infiltration(mm/hr)	Effective[1] Unfactored Infiltration (mm/hr)
1A (northern) Aea north of Moyard	BH11-22 & BH16-22	109.5	43.8
1A (southwest) Area south of Moyard and west of Street 7	BH11-22 & BH18-15	88.5	35.4
1A (southeast) Area south of Moyard and east of Street 7	BH8-22 & BH9-22	72.5	28.9

Area No.	Borehole No	Average Unfactored Infiltration(mm/hr)	Effective[1] Unfactored Infiltration (mm/hr)
1B	BH17-22 & BH18-22	84.0	33.6

Note[1]: Simulated unfactored infiltration was calculated by applying a safety factor of 2.5 on the average unfactored infiltration rate.

3.13.1.2 Post-Development Water Budget Findings

The post-development water budget analysis was carried out while accounting for EES reaches being implemented in the following areas (refer to Figure 9):

- All of Area 1A.
- All of Area 1B.

In terms of simulation of the EES in the above-noted areas, the same configuration and approach used in all stages of the Quinn's Pointe Subdivisions has been extended for the S1 Area. The configuration is based on the following:

- 1000 mm thick clear stone envelope, surrounded by geotextile
- 2-300 mm diameter perforated pipes, surrounded by geotextile
- Width of clear stone envelope is based on the following:
  - ✓ Sewer diameter plus 450 mm clearance on either sides for 900 mm diameter sewer or smaller
  - ✓ Sewer diameter plus 500 mm clearance on either side for sewers over 900 mm diameter.

The analysis was completed using Paterson's unfactored infiltration rates (refer to Section 3.13.1.1). A comparison was made between the existing and post-development water budgets with the modelling approach and assumptions summarized above.

Table 10: Post-Development Water Budget

Annual Water Budget Component	Annual Average Depth to Jock River (mm)	Annual Average Depth to Mud Creek (mm)	Annual Average Depth to Rideau River (mm)	Area Weighted Total (mm)	Budget %
Precipitation	864 [864]	864 [864]	864 [864]	864 [864]	100% [100%]
Evapotranspiration	248 [509]	262 [531]	252 [509]	249 [513]	29% [59%]
Infiltration	301 [296]	214 [314]	274 [286]	297 [297]	34% [34%]
Surface Runoff	316 [83]	389 [60]	339 [0]	319 [61]	37% [7%]

*Values in brackets ([ ]) represent pre-development values for purpose of comparison with post-development water budget values.

The above simulation results show that the infiltration strategy, as depicted on both MST in Appendix K capable in maintaining the existing condition infiltration rate of 34%.

Given that the existing water budget is maintained under post-development conditions with the proposed infiltration measures, the infiltration requirements of the CLI-ECA (Appendix A) will be achieved.

3.13.2 Dual Drainage

3.13.2.1 Minor System

It was generally assumed that the USF elevations are approximately two (2) meters below the road centerline grades. However, in cases where the storm sewers are relatively shallow, such as to prevent the EES from being located within the groundwater, risers and appropriate grading will be required to ensure a minimum freeboard of 300 mm is maintained between the sewer HGL and the USF elevations of the units.

3.13.2.2 Major System

The dual-drainage analysis was reviewed in relation to the performance of the major overland system. Elevations above the major system nodes have been extracted and shown in Table 11. As shown below, there is no ponding in the 1:2-year event and there is no ponding in the 1:5-year in the industrial sites or along collector roads. Moreover, the depth of flow along the major system is below 350 mm during the 1:100-year event. Simulation results for other storm events, including climate change and historical storms, have been summarized in Appendix L.

Table 11: Major Overland Flow Results

Major System Node	1:2 yr - 3 hr Chi Ponding Depth (mm)	1:2 yr - 24 hr Ponding Depth (mm)	1:5 yr - 3 hr Chi Ponding Depth (mm)	1:5 yr - 24 hr Ponding Depth (mm)	1:100 yr 3 hr Chi Ponding Depth (mm)	1:100 yr - 24 hr SCS Ponding Depth (mm)

S_540-536	10	10	60	60	210	200
S_629-622	10	10	50	50	180	160

As part of the MSS level modelling, only the critical sewers and trunk sewers are modelled to ensure that the site is serviceable and to which further details are typically refined during conceptual/detailed designs. However, to ensure accuracy and conservativeness within such a model, the time of concentration calculated in the Storm Sewer Design Sheet for each downstream sewer reach within a tributary area was used to calculate the Rationale Method minor system inflow from major system node to the minor system. As a result, in some instances Table 11 above will show that there is ponding in some areas during the 1:2-year event and in the 1:5-year in the industrial sites or along collector roads. However, once the model is further refined during the detailed design stage, drainage areas will be further delineated and will be tributary to individual storm sewer reaches in which case the rational inflow for each area will be calculated based on a 10 minutes time of concentration and will in turn eliminate any ponding during the 1:2-year event and in the 1:5-year in the industrial sites or along collector roads. Moreover, the depth of flow along the major system is below 350 mm during the 1:100-year event. Simulation results for other storm events, including climate change and historical storms, have been summarized in Appendix L

3.13.3 Proposed Dry Pond Expansion

An existing spill-over area exists within the S1 Area, in the southeastern portion of Block 61. This facility was constructed as part of Quinn's Pointe Subdivision to capture major overland flow being directed westerly given that it could not cross future Greenbank Road. The existing spill-over area is serviced by an existing outlet sewer (900 mm diameter storm sewer) discharging to the Inver Lane 1500 mm diameter storm sewer system. The 900 mm diameter outlet sewer was sized to empty the spill-over pond during infrequent storm events.

Drawings KS1, MST, POND and D2 provide the configuration of the proposed end-of-pipe facility consisting of the following elements (refer to Section 3.11.5 for additional details and Appendix F for information):

- Pre-treatment device - Defender Model FD-8
- By-pass manhole (flow splitter) forcing the 22 mm to the filtration dry pond while excess flows to by-pass the filtration dry pond and would be conveyed to the downstream dry pond.

  Filtration Dry Pond:
  - Surface Area at Spill of 100.8m: 2,235 m^2
  - Volume of Infiltration Dry Pond: 1,418 m^3
  - 700 mm thick of amended soil (bio-retention soil media)
  - 350 mm thick clear stone
  - 150 mm diameter sub-brains
  - Geosynthetic membrane

  Dry pond:
  - Volume prior to spill: 28.790 m^3
  - Outlet elevation: 98.45 m
  - Internal sloping: 1.0-1.3%
  - 3 m wide perimeter access road
  - Major overland flow route: Barnsdale Road (events > 100-year)

Once storm flows have been filtered by the filtration dry pond, they will merge with the treated flows from the EES and Industrial Lands and will be controlled by the existing outlet consisting of the 900 mm diameter storm sewer system. Table 12 and Table 13 (below) summarize key parameters relating to the configuration of these facilities.

Table 12: Filtration Dry Pond Configuration and Results

Pond Configuration	Filtration Dry Pond
Pond Invert (m)	100.10
Footprint Area (m^2) @ 100.10 m	1,822
Top of Spillway Area (m^2) @ 100.80 m	2,235
Top of Bank (m) at Spill	100.80
Active Storage Depth (m)	0.70
Elevation of 3 m wide Spillway (m)	100.80
Outlet Diameter (m)	N/A
Drawdown Time (hrs) - 4-hour 22mm Design Storm	17
Overall effective filtration rate (mm/hr)	50.4

Table 13: Expanded Dry Pond Configuration and Results

Pond Configuration	Expanded Dry Pond
Pond Invert (m)	98.45
Modelled Release Rate (m^3/s) - 3-hour Chicago Storm	0.349
Pond Top of Bank (m)	100.8
Active Storage Depth (m)	2.35
Freeboard to adjacent building envelopes(m)	>0.3
Outlet Bottom Orifice Elevation (m)	98.45
Outlet Bottom Orifice Diameter (m)	0.335
Outlet Upper Orifice Elevation (m)	100.8
Outlet Upper Orifice Dimensions (m)	250 mm x 900 mm
Drawdown Time (hrs) - 4-hour 22mm Design Storm	18
Surface Area (ha)	3.66

The operation of the filtration pond is provided in Table 14 below for the 3-hour Chicago storm distribution and Table 15 for the 24-hour SCS storm Distribution.

Table 14: Filtration Pond Operation (3-hour Chicago Storm)

Event	Max HGL (m)	Max Depth (m)	Total Inflow (L/s)	Peak Filtration Rate (L/s)	Max Volume (m3)
4-hour, 22 mm	100.67	0.57	768	26	1,139
1:2 year	100.90	0.80	1,729	26	1,654
1:5 year	100.95	0.85	2,190	26	1,764

Event	Max HGL (m)	Max Depth (m)	Total Inflow (L/s)	Peak Filtration Rate (L/s)	Max Volume (m3)
1:100 year	101.06	0.96	5,807	26	2,009
1:100 year + 20%	101.10	1.00	8.047	26	2,122

Table 15: Filtration Pond Operation (24-hour SCS Type II Storm)

Event	Max HGL (m)	Max Depth (m)	Total Inflow (L/s)	Peak Filtration Rate (L/s)	Max Volume (m3)
1:2 year	100.92	0.82	1,926	26	1,698
1:5 year	100.95	0.85	2,210	26	1,768
1:100 year	101.04	0.94	4,964	26	1,959
1:100 year + 20%	101.08	0.98	6,837	26	2,066

The operation of the dry pond is provided in Table 16 below for the 3-hour Chicago storm distribution and Table 17 for the 24-hour SCS storm Distribution.

Table 16: Dry Pond Operation (3-hour Chicago Storm)

Event	Max HGL (m)	Max Depth (m)	Total Inflow (L/s)	Peak Minor System Release Rate (L/s)	Max Volume (m3)
4-hour, 22 mm	99.40	0.95	1,974	201	2,738
1:2 year	99.77	1.32	4,243	248	7,110
1:5 year	100.08	1.63	6,785	282	12,370
1:100 year	100.80	2.35	11,980	349	28,730
1:100 year + 20%	100.98	2.53	14,540	495	33,230

Table 17: Dry Pond Operation (24-hour SCS Type II Storm)

Event	Max HGL (m)	Max Depth (m)	Total Inflow (L/s)	Peak Minor System Release Rate (L/s)	Max Volume (m3)
1:2 year	99.785	1.34	4,499	249	7,319
1:5 year	100.056	1.61	7,000	279	11,870
1:100 year	100.687	2.24	10,780	340	26,020
1:100 year + 20%	100.915	2.47	12,990	426	31,630

The modelling results demonstrate that the pond contains flow in up to the 1:100-year event. The maximum water level in the pond is 100.8 m, which provides a minimum 300 mm freeboard to adjacent properties (Quinn's Pointe) and a controlled spill occurs in events greater than the 1:100-year storm event onto Barnsdale Road.

3.13.4 Off-Site Peak Flow Discharges

3.13.4.1 General

The proposed storm servicing strategy outlined herein was developed to ensure that there are no net increases in off-site peak flows at any of the discharge points. Due to the constraints of the Thomas Baxter Municipal Drain—the natural receiving outlet with limited conveyance capacity and shallow elevation—the storm servicing approach for most of the S1 Area involves capturing post-development drainage within a storm sewer system and redirecting it to a proposed on-site end-of-pipe facility in Block 61. Outflows from this facility would then discharge into the existing Quinn's Pointe storm sewer system at a rate equal to the flow rate identified for the Quinn's Pointe Subdivision under buildout conditions.

This storm servicing approach, referred to as a "disconnection," aligns with the secondary objective of facilitating approval timelines under the Ontario Drainage Act by minimizing the release of post-development drainage to the Thomas Baxter Municipal Drain. This approach also aligns with a previously completed disconnection of an area (refer to 2018 BSUEA MSS) of which was tributary to the Thomas Baxter Municipal Drain and later formalized by RCI in its report entitled "Engineer's Report for the Subsequent Disconnection Thomas R. Baxter Municipal Drain (October 2021)".

Section 3.13.5.3 (below) discusses in greater detail the area being contemplated for disconnection from the Thomas Baxter Municipal Drain. An area of 10.7 ha was initially disconnected as reported in the 2018 BSUEA MSS while the current proposal is to extend an additional disconnection of a 59.8 ha area. This value represents a reduction when compared to the previous MSS Addendum (October 2025) shown as 65.8 ha, as the flow pattern of the southern woodlot (identified as a good candidate for conveyance as natural feature) unchanged under post-development conditions as it will continue to sheet flow towards the Borrisokane Road open ditch system.

3.13.4.2 Hydrological Analysis and Simulation Results

In addition to the comparison of peak flows at the boundary of the Quinn's Pointe Subdivision, this hydrological analysis was refined to assess peak flows and runoff volumes at two (2) locations along the Borrisokane Road/Barnsdale Road open ditch systems, as well as at the boundary culvert leading to the headwater of the Thomas Baxter Municipal Drain.

The refined hydrological analysis considered a range of storm events, including the 4-hour Chicago 25 mm storm (the industry-standard water quality event) and typical events ranging from the 1:2-year to the 1:100-year return periods. The analysis also accounted for half of the Barnsdale Road ROW and the eastern half of the Borrisokane Road ROW, as detailed in Figure 5-2 of JLR's Existing Conditions Report (Appendix B).

Given that the SWMHYMO platform used in 2017 for the Existing Conditions for the BSUEA (as reported in JLR's ECR - S1 Area) is no longer compatible with current computer and operating systems, the pre-development analysis was revised using the PCSWMM platform, which aligns with the Addendum post-development condition hydrologic analysis.

The refined analysis was conducted under both pre-development and post-development conditions, with peak flows and runoff volumes extracted at several discharge points along the boundary. Figures entitled *Pre-Development Model Schematic* and *Post-Development Model Schematic* are included in Appendix H.

Peak flows and runoff volumes were generated at the following discharge points:

1. **Existing Quinn's Pointe 900 mm diameter storm sewer:** Peak flows are summarized in Table 18.
2. **Borrisokane open ditch/culvert system** – **Node "EXD_9"** (refer to Table 19 and Table 20)
3. **Borrisokane/Barnsdale Road open ditch/culvert system** and **Node "EXD_12"** (refer to Table 21 and Table 22)
4. **Thomas Baxter Municipal Drain** immediately downstream of the merging contributions between the Barnsdale Road and Borrisokane Road open ditch systems, at **Node "Municipal Drain"** (Table 23 and Table 24), refer to Appendix H for Schematics.

The P*re-Development Model Schematic* and *Post-Development Model* Schematic is contained in Appendix H.

Table 18: Off-Site Peak Flow - Quinn's Pointe 900 mm diameter Sewer

Development Condition	1:100-year Peak Flow (L/s) 3-hour Chicago	1:100-year +20% Peak Flow (L/s) 3-hour Chicago
Quinn's Pointe 900 mm diameter Sewer		
Existing Condition	349	499
Post-Development Condition	349	495

Peak flows and runoff volumes have been summarized under the 4-hour 25 mm storm as well as under the SCS Type II storm, during events ranging between 1:2-year to 1:100-year as follows:

- Table 19 and Table 20 at Node "EXD_9"
- Table 21 and Table 22 at Node "EXD_12"
- Table 23 and Table 24 at Node "Municipal Drain"

Refer to **Appendix H** for pre- and post-development PCSWMM Schematics.

Table 19: Peak Flow Comparison at Node EXD_9

Note: The values in parentheses are the reduction expressed in percentages

The following conclusions can be drawn from the review of the above summary Tables:

- The 1:100-year post-development peak flows released to the existing Quinn's Pointe storm sewer are maintained at levels identified for the Quinn's Pointe Subdivision at the build-out conditions (Table 18)
- The lower peak flows and runoff volumes at Node EXD_9 (Table 19 and Table 20) are attributable to a reduction in contributing drainage area from 22.0 ha under pre-development conditions to 9.0 ha under post-development conditions.
- The lower peak flows and runoff volumes at Node EXD_12 (Table 21 and Table 22) are attributed to a reduction in contributing drainage area from 73.2 ha under pre-development conditions to 13.4 ha under post-development conditions.
- As a result of the reductions in contributing drainage area noted above, post-development peak flows and runoff volumes discharging to the Borrisokane Road open ditch system and to the Borrisokane Road/Barnsdale Road at Nodes EXD_9 and EXD_12, respectively are lower than pre-development values for all storm events, as summarized in the above Tables.
- Peak flows and runoff volumes at the Municipal Drain (Table 23 and Table 24) reflect a reduction in the contributing drainage area from 80.3 ha under pre-development conditions to 20.5 ha under post-development conditions. Accordingly, Table 23 ands Table 24 indicate decreases in both peak flows and runoff volumes for all storm events.

3.13.5 Impact of Post-Development Drainage Modifications

3.13.5.1 General

The proposed drainage limit modifications will alter the hydrological regime as highlighted in Section 3.13.4.2. In all cases, the proposed disconnection reduces both peak flows and runoff volumes at the analyzed off-site discharge points.

The following sections provide an impact assessment of the modified hydrological regime at key locations:

- Borrisokane Road open ditch system
- Barnsdale Road open ditch system
- Thomas Baxter Municipal Drain
- Downstream Fisheries

3.13.5.2 Borrisokane Road Open Ditch System

The Borrisokane Road open ditch system is part of Highway 416's right-of-way (ROW), which is owned and operated by the Ministry of Transportation (MTO). Therefore, any modifications to the hydrological regime of the Borrisokane Road open ditch system should be reviewed by MTO.

As reported in Section 3.13.4.2, peak flows and runoff volumes were evaluated at the downstream end of the Borrisokane Road open ditch system at Node EXD_9 (Appendix H for Schematics). Simulation results indicated the following:

- Post-development peak flows are reduced by ±56% and 6% at Node EXD_9 during the 4-hour 25 mm storm and 1:100-year storm, respectively. Similarly, runoff volumes are reduced by ±32% and ±19% during the 4-hour 25 mm storm and 1:100-year event, respectively.

Based on the above simulation results, the proposed drainage modifications (i.e., disconnection) will provide relief to the Borrisokane Road open ditch system as both peak flows and runoff volumes will be reduced. Therefore, there are no anticipated adverse impacts along this drainage system owned and operated by MTO.

3.13.5.3 Barnsdale Road Open Ditch - Headwater Features

An Environmental Impact Statement (EIS) was prepared by Arcadis, with the latest version of the Report issued by Fotenn (March 3rd, 2026). As part of this EIS, a Headwater Drainage Feature (HDF) Assessment identified three (3) reaches along Barnsdale Road—BN-1-A, BN-1-1B, and BN-2-A—which received a management recommendation of mitigation requiring the following:

> *The reaches identified should have their functions replicated or enhanced through improved conveyance measures, with flows directed to the appropriate downstream receiver.*

A review of topography shows that the invert of the Barnsdale Road open ditch system varies from approximately 99.6 m at BN-1-A to 98.7 m at BN-2-A, matching the measured edge-of-water elevation of the adjacent man-made pond. Most reaches identified in the EIS would appear to be groundwater-fed rather than being fed by the northern areas, based on measured water elevations shown on the topographical map. Additionally, as a secondary source of inflow, the alignment of these HDFs coincide with the Barnsdale Road open ditch system, which receives runoff from half of the Barnsdale Road ROW, including about 4.5 m wide asphalt strip and a gravel shoulder at a typical 3:1 side slope. While part of the S1 Area is proposed to be

disconnected from BN-1-A, BN-1-1B, and BN-2-A, runoff from the Barnsdale ROW, including the shoulder and groundwater contribution will be maintained, allowing these reaches to function as they do under existing conditions.

Simulation of runoff volume at BN-2-A (EXD_12), as indicated in the above Table, shows a 25% reduction during the 4-hour 25 mm storm, which should not adversely impact the HDFs given the above-noted sources of inflow will be maintained. However, the EIS provided mitigation measures (Section 8.2.2) should any construction activities be planned to take place below the high-water mark of the HDFs. These are the following:

- Due to their classification as indirect fish habitat, any direct construction below the high-water mark in Features BN-1, BN-2, BN-3, and Feature 416 will require authorization from DFO through the submission of a Request for Review.
- Direct construction in BN-1, BN-2, BN-3, and Feature 416 and at elevations below the high-water mark should incorporate shallow groundwater measures as well as LID construction practices.
- No work within the high-water mark outside of the fish timing window.

No direct construction activities are envisioned to impact directly any of the above-noted HDFs. The following activities are however anticipated:

- Construction of the residential subdivision and infrastructure within the S1 Area, located outside of the HDFs.
- Construction of the Barnsdale Road 375 mm diameter sanitary sewer extension, planned from the existing stub (at Bundoran Place) to Street 17, and northerly. The alignment of this sanitary sewer extension is away from BN-1-A.

Upcoming Infrastructure Work

It is important to note that the MTO and the City of Ottawa plan to widen this section of Barnsdale Road in the future, as an ongoing Class Environmental Assessment was initiated in 2025 by the city. It is unknown at this time whether a rural or urban cross-section will be selected. However, widening will increase the paved surface and encroach on HDF reaches BN-1-A, BN-1-1B, and BN-2-A. Consequently, the function of these reaches will significantly be altered or completely removed as widening occurs over the next 5 to 10 years. Until such time, the function of these HDFs will remain due to groundwater inflow combined with surface runoff from Barnsdale Road.

3.13.5.4 Thomas Baxter Municipal Drain

The partial disconnection of approximately 59.8 ha results in reductions to both peak flows and runoff volumes at the headwaters of the Thomas Baxter Municipal Drain (Node “Municipal Drain”), as illustrated on the Pre-Development and Post-Development Model Schematics provided in Appendix H.

Peak flows and runoff volumes at the Municipal Drain (Table 23 and Table 24) similarly reflect a reduction in the contributing drainage area from 80.3 ha under pre-development conditions to 20.5 ha under post-development conditions. Accordingly, Table 23 and Table 24 indicate decreases in both peak flows and runoff volumes for all storm events. Accordingly, the partial

disconnection is not anticipated to adversely affect the Municipal Drain. Subject to approval, the proposed modifications to the hydrologic regime will be documented in an updated Engineer's Report prepared in accordance with the Drainage Act (Section 78, Chapter D.17, R.S.O. 1990).

As shown on Figure 7, the total study area of approximately 69.9 ha is comprised of two different watersheds: Mud Creek Subwatershed and the Jock River Subwatershed. Under existing condition, most of the study area is tributary to the Thomas Baxter Municipal Drain/Mud Creek Subwatershed and a small section in the Northeast corner is tributary to the Jock River. Under post-development condition a partial disconnection of approximately 59.8ha from the Mud Creek Subwatershed is captured tributary to the proposed dry pond which in turn tributary to the Jock River. A breakdown of the tributary areas under pre- and post-development conditions are summarized in the Table below:

Table 25: Study Area Breakdown by Watershed

Subwatershed	Pre-Development Area (ha)	Post-Development Area (ha)
Thomas Baxter Municipal Drain/Mud Creek	66.5	6.7
Jock River	3.4	63.2

3.13.5.5 Downstream Fisheries

Simulation results summarized in Section 3.14 demonstrate reductions in both peak flows and runoff volumes at the headwaters of the Thomas Baxter Municipal Drain, immediately downstream of the southern limit of the Barnsdale Road right-of-way. From a fisheries perspective, the 4-hour, 25-mm storm event is considered more influential than higher return period events, as it occurs approximately four to five times annually, compared to the less frequent 2-year and 100-year events.

Under post-development conditions, the runoff volume associated with the 4-hour, 25-mm rainfall event was estimated at approximately 1,293 m^3, representing a reduction of about 335 m^3 (approximately 21%) relative to pre-development conditions. As no fish habitat is present at the headwaters of the Thomas Baxter Municipal Drain near Barnsdale Road, this reduction in runoff volume is not expected to adversely affect downstream fish communities, which are primarily located near the confluence with Mud Creek.

LiDAR analysis indicates that the total drainage area of the Thomas Baxter Municipal Drain at its confluence with Mud Creek is approximately 883 ha, whereas the study area reflects a tributary area of approximately 80.3 ha—representing less than 10% of the total contributing area at Mud Creek. As additional runoff contributions occur along the reach between Barnsdale Road and Mud Creek, the relative influence of the reduced runoff volume diminishes as flow from the remaining ±803 ha of largely unchanged drainage area is incorporated. Consequently, hydrologic conditions in proximity to the Mud Creek fish communities are expected to remain effectively unchanged.

Consistent with this assessment, Section 8.2.2 of the EIS concludes that conditions near the Mud Creek fish communities are anticipated to remain virtually unchanged and align with the HDF Assessment mitigation objective to maintain or replicate existing conveyance functions

toward appropriate receivers. Accordingly, the proposed disconnection is not expected to result in adverse impacts to fish communities near Mud Creek.

3.13.6 Water Quality for the Constraint Areas

Calculations presented in Section 3.11.6 demonstrate that water quality control requirements are satisfied for all areas serviced by an EES, as this system exceeds the infiltration criteria outlined in Table 3.2 of the Stormwater Management Planning and Design Manual (SWMPDM). Furthermore, the infiltration strategy detailed in Section 3.13.1 is shown to be comparable to the existing condition water budget. Accordingly, the proposed stormwater servicing approach satisfies the requirements of the CLI-ECA.

Water quality treatment for areas identified as constraints on Figure 10 will be provided at both storm sewer inlets (STMH501 and STMH554) to the expanded dry pond (refer to Drawing MST in Appendix I). As infiltration measures have been implemented to the maximum practical extent and post-development water balance conditions are comparable to existing conditions, the requirements of the CLI-ECA are met. For the areas noted as constraints, water quality will be achieved via a treatment train approach; a pre-treatment MTD (ETV sized) and filtration dry pond sized to provide on its own an 80% TSS removal.

3.14 Stormwater Summary and Recommendations

This Addendum presented a storm servicing strategy, which was based on the extension of the approved solution described in the 2018 BSUEA MSS. This solution consisted of a traditional storm sewer system, sized based on the SDG, combined with infiltration measures that were developed to the maximum extent possible while recognizing a series of constraints described in Section 3.7.1 and depicted on Figure 9. To supplement this system, the areas referenced as constraints will be serviced by a treatment train approach combining a pre-treatment MTD with a filtration dry pond.

The conceptual servicing design was found to fulfill the following:

- Achieves the prescribed flow rate along the existing 900 mm diameter storm sewer within Quinn's Pointe.
- Achieves the minimum 300 mm freeboard across the S1 Area (residential).
- Achieves flow depths of 350 mm or less along the major overland system of the S1 Area. Achieves the infiltration requirements as specified in Appendix A of the CLI-ECA as the existing condition water budget will be maintained.
- Achieves the filtration requirements as specified in Appendix A of the CLI-ECA as the water quality control will be met.
- Achieves a comparable water budget to existing levels.
- Peak flow and runoff volume reductions to the Borrisokane Road open ditch system, to the Thomas Baxter Municipal Drain and Barnsdale Road open ditch system.

It is recommended that storm servicing in the S1 Area be carried out based on:

- ✓ Conventional storm sewers along with an EES on local roads, when permitting
- ✓ Lot-level sub-surface infiltration measures for each building within the Industrial lands.
- ✓ Areas defined as constraints to be serviced by a treatment train approach, combining a pre-treatment MTD with a filtration dry pond.

Simulation results indicate that the EES along local roads is sufficient to achieve an enhanced level of protection when sized to capture 22 mm of runoff. In contrast, roadway areas not serviced by an EES require a filtration alternative prior to discharging off-site. The recommended filtration solution as identified by the screening process is to provide a filtration dry pond supplemented by pre-treatment MTD.

Overall outflows from both trunk storm sewers are then controlled by the end-of-pipe facility dry pond discharging to the existing sewers in Quinn's Pointe.

Simulation results have revealed that the EES along local roads is sufficient when sized for 22 mm in meeting an enhanced protection level. Similarly, the filtration dry pond which uses the same infiltration principle is sufficient to meet the CLI-ECA.

4.0 Wastewater Servicing

4.1 Background

The wastewater collection system within the S1 Area has been conceptually sized to convey flows to existing gravity sanitary sewers within the Barrhaven South Community. These trunk sanitary sewers ultimately discharge the captured flows to the 900 mm diameter trunk sanitary sewer located along Greenbank Road. From that point, wastewater is then conveyed to the South Nepean Collector, followed by the West Rideau Collector, which ultimately outlets to the Robert O. Pickard Environmental Centre (ROPEC), where it is treated prior to being discharged into the Ottawa River.

In JLR's Serviceability Study (2019), it was demonstrated that the parcels adjacent to the BSUEA, which includes the S1 Area, could be serviced through extensions of the existing and proposed infrastructure in the area. From a wastewater servicing perspective, it was confirmed that the S1 Area could be serviced via a connection to the existing 375 mm diameter sanitary sewer located on Barnsdale Road, south of the existing Quinn's Pointe Stage 4 (refer to Figure 11 and Figure 12).

More recently, the 2025 ECR (Appendix B) identified several critical sewers where residual capacities of the existing trunk sanitary sewer network were to be reviewed to confirm that they could accommodate the increase in peak wastewater flows from the S1 Area. These critical pipe reaches are summarized in Table 26 below.

Table 26: Critical Residual Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Limiting Pipe Reach
Barnsdale Road	MH203 to MH202
Greenbank Road	MH200C to MH45
Greenbank Road	MH435A to MH501A

The wastewater servicing strategy for the S1 Area was developed in accordance with the design criteria outlined in the OSDG and subsequent technical bulletins, while also respecting the capacity limitations of the existing downstream infrastructure.

4.2 Wastewater System Servicing

4.2.1 Design Criteria

Trunk sanitary sewers servicing the S1 Lands were designed in accordance with the following criteria from the ODSG and subsequent Technical Bulletins:

Table 27: Sanitary Design Criteria

Design Criteria	Design Value
Residential Average Flow	280 L/cap/day
Residential Peaking Factor	Harmon Formula x 0.8
Light Industrial Average Flow	28,000 L/gross ha/day
ICI Peaking Factor (1)	1.0/1.5
Total Infiltration	0.33 L/s/ha
Minimum Velocity	0.6 m/s
Maximum Velocity	3.0 m/s
Manning Roughness Coefficient (for smooth wall pipes)	0.013
Minimum Allowable Slopes	Varies
Population Density	Single Family: 3.4 ppu Townhouse: 2.7 ppu

(1) 1.5 if ICI Contribution > 20%, 1.0 otherwise.

4.2.2 Residual Capacities in the Existing Sanitary Sewer Network

As part of the BSUEA MSS (2018), a Master Sanitary Design Sheet was developed to assess the available capacity of the existing sanitary sewer infrastructure within the BSUEA, and further downstream in the existing areas. This design sheet was subsequently refined during the 2019 Serviceability Study and further updated in the ECR (2025) to incorporate the most recent design flow data for Quinn's Pointe Stages 2 through 5, as well as the future S1 and S2 Areas. The S2 Area represents a planned expansion located east of Greenbank Road and north of Barnsdale Road which is also in the MSS preparation stage.

The Serviceability Study (2019) identified segments of the existing network with potential capacity limitations. This analysis was further refined in the ECR (2025), with a specific focus on the S1 Area. The sanitary trunk sewers evaluated for this area were located along Barnsdale Road and Greenbank Road. The limiting pipe reaches identified in this report are summarized in Table 26.

At the time of the preparation of the ECR (2025), the Concept Plan for the S1 Area was at a preliminary stage thus the available servicing capacities of the existing system have been re-evaluated in Section 4.4 to reflect the most recent iteration of the Concept Plan (Appendix D).

4.3 Wastewater Collection System Strategy

4.3.1 Phasing

As shown in the preferred Concept Plan (Appendix D), development of the S1 Area is proposed to proceed in three sequential residential phases: Phases 6, Phase 7, and Phase 8, including two industrial land parcels totaling 13.22 ha to the north and 3.19 ha to the south. The ultimate

sanitary outlet for the entire S1 Area is located within Phase 6 at Barnsdale Road at Street No. 15. Accordingly, the downstream sewer infrastructure as part of Phase 6 will be designed to accommodate ultimate buildout conditions, including all residential phases and both industrial lands. By sizing the initial phase infrastructure to meet full future capacity requirements, the system will inherently satisfy the servicing needs of all interim development phases.

4.3.2 Proposed Sewer System Layout and Sizing

As shown in the Concept Plan (Appendix D), the wastewater collection system for the S1 Area is intended to service single family units, townhouse blocks, the industrial lands and a park block.

The proposed sanitary sewers within the S1 Area have been conceptually sized based on the design criteria listed in Table 27 and the drainage areas depicted on Drawing MSAN in Appendix K. A trunk sanitary sewer system layout has been developed in accordance with the latest Concept Plan (Appendix D). Within the S1 Area, there are two (2) designated collector roads which are:

- Elevation Road: This roadway serves as the north-south collector from Kilbirnie Drive to Cappamore Drive; and
- Cappamore Drive: This roadway serves as the east-west collector from the woodlot, potentially conveyed as natural feature, which is adjacent to the Industrial Lands to the existing Quinn's Pointe Stage 4.

Since Elevation Road and Cappamore Drive are the designated collector roads within the S1 Area, the trunk sanitary sewers are proposed to follow their alignments within the Study Area.

The remainder of the sanitary sewer network is to follow the configuration of the local road system, with careful consideration given to maintaining minimum flow velocities, ensuring adequate cover, and avoiding infrastructure conflicts. The sanitary sewer layout is to be developed in coordination with the stormwater and watermain networks.

The Master Sanitary Sewer Design Sheet, prepared as part of the ECR, included the population and corresponding flows for the S1 Area (refer to Appendix I). It also shows trunk sanitary sewer sizing. Based on this assessment, wastewater from the S1 Area is expected to be conveyed primarily through an internal sanitary network consisting of sanitary sewers ranging from 200 mm to 375 mm in diameter. Final pipe sizing will be confirmed during detailed design.

4.3.3 Barnsdale Road Outlet

The 2019 Serviceability Study evaluated potential sanitary sewer connections for the S1 Area and concluded that servicing could be achieved via a connection to the existing 375 mm diameter sanitary sewer located on Barnsdale Road, south of the Quinn's Pointe Stage 4 development. This recommendation was based on the available residual capacity within the Barnsdale Road sewer infrastructure. Additionally, the Master Sanitary Sewer Design Sheet (refer to Appendix I) included in the report confirmed that the existing sanitary sewers on Cappamore Drive do not have sufficient capacity to accommodate additional flows.

4.4 Impact on Downstream System

The ECR (2025) included the refinement of the BSUEA Master Sanitary Design Sheet to assess the available capacity of the existing sanitary sewer infrastructure. This analysis incorporated the most up-to-date design flow data for Quinn's Pointe Stages 2 through 5, along with projected flows for the future S1 and S2 Areas.

This Master Sewer Design Sheet has been refined further as part of this assessment to include design flows from the most recent iteration of the Concept Plan (Appendix D). With the addition of the S1 and S2 Areas, the calculated theoretical peak wastewater flows were found to be within the available residual capacities of the existing downstream sanitary sewer (refer to Master Sanitary Design Sheet in Appendix I). Consequently, no further infrastructure improvements are required along the existing downstream system. Table 28 provides a summary of the impact of the S1 and S2 areas to the critical pipe reaches in Table 26.

Table 28: Residual Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Limiting Pipe Reach	Residual Capacity
Barnsdale Road	MH203 to MH202	118.4 L/s
Greenbank Road	MH200C to MH45	11.5 L/s
Greenbank Road	MH435A to MH501A	98.8 L/s

4.5 Wastewater Summary and Recommendations

The wastewater collection system illustrated in Drawing MSAN in Appendix K and the accompanying Master Sanitary Sewer Design sheet (Appendix I) has been conceptually sized based on the design criteria outlined in Table 27, while accounting for the residual capacities of the pipe segments identified in Table 28.

As noted in Section 4.3, the layout of the trunk sanitary sewer system has been developed in accordance with the most recent Concept Plan, with Elevation Road and Cappamore Drive designated as the primary north-south and east-west trunk sewers, respectively.

It is expected that wastewater generated by the S1 Area can be accommodated by a series of 200 mm diameter sanitary sewers as shown in the Master Sanitary Sewer Design Sheet (Appendix I). Furthermore, the calculated theoretical peak wastewater flows for the S1 Area were found to be within the available residual capacities of the existing downstream sanitary sewer while accounting for the projected flows from the S2 Area (refer to Appendix I). Consequently, no further infrastructure improvements are required along the existing downstream system.

5.0 Water Distribution

5.1 Background

The 2018 BSUEA MSS reviewed and evaluated servicing options with the identification of preferred trunk watermains, which were subsequently constructed. This Addendum, prepared as an extension to the 2018 BSUEA MSS, identifies feedermains to support the urbanization of the S1 Area.

In 2019, the Serviceability Study water supply assessment confirmed that extensions of existing watermains would provide potable water that met the design criteria and objectives listed in Section 4.2.2 of the Ottawa Design Guidelines for Water Distribution (December 2025).

The review of the existing and future planned watermains was carried out as part of the 2025 ECR (Appendix B). Figure 13 depicted the existing and planned watermains along the boundary of the S1 Area. This review has shown that the current urban development to the east of the Study Area (i.e., Quinn's Pointe Subdivision) and to the north of the Study Area (i.e., The Ridge Subdivision) are both serviced by the municipal distribution system, which draws its water from the Ottawa River at both the Britannia and Lemieux Water Purification Plants. From those purification plants, potable water is distributed via a series of feedermains and water booster stations. The City of Ottawa water distribution system is planned based on achieving the following design objectives:

- Quantity: sufficient water at sufficient pressure (Section 4.2.2 of the Ottawa Design Guidelines for Water Distribution)
- Quality: safe drinking water to the required standards (Section 4.1 of the Ottawa Design Guidelines for Water Distribution).
- Reliability: to ensure water supply under emergency conditions.
- Effectiveness and affordability: to reduce lifecycle costs being sustainable in the long term.

Three (3) feedermains service the Barrhaven South Community from the Barrhaven reservoir, which are as follows:

- a 406 mm main along Greenbank Road
- a 406 mm main along Cambrian Road; and
- a 305 mm feeder main along River Mist Road

Two (2) sections of the planned feedermains were also recently constructed as follows:

- 305 mm feedermain along New Greenbank Road, from Barnsdale Road to Kilbirnie Road.
- 406 mm feedermain on Cambrian Road, from Elevation Road to existing Greenbank Road.

Future planned feedermains are as follows:

- 305 mm feedermain on Kilbirnie Drive, from New Greenbank Road to the eastern perimeter of the S1 Area, including a connection to Obsidian Street.

5.2 Water Servicing

5.2.1 Design Criteria

The Ottawa Design Guidelines for Water Distribution (December 2025) require that all new development additions to the public water distribution system be designed to conform to the following:

- In general conformance with the MOE Design Guidelines for Drinking-Water Systems the desired range of system pressures should be approximately 350 to 480 kPa (50 to 70 psi) and not less than 275 kPa (40 psi) during normal operating conditions.
- Where fire flow has been provided; during periods of maximum day and fire flow demand the residual pressure at any point in the distribution system shall not be less than 140 kPa (20 psi).
- In accordance with the Ontario Code & Guide for Plumbing, the maximum pressure at any point in the distribution system in occupied areas outside of the public right-of-way shall not exceed 552 kPa (80 psi.)
- The maximum pressure at any point in the distribution system in unoccupied areas shall not exceed 689 kPa (100 psi.)
- Feedermains, which have been provided primarily for the purpose of redundancy, shall meet, at a minimum, the basic day plus fire flow demand.

In addition to the above targets, servicing should be carried out to minimize the use of dead-end watermains.

5.2.2 Phasing

As shown in the preferred Concept Plan (Appendix D), development of the S1 Area is proposed to proceed through three sequential residential phases: Phase 6 including an industrial land parcel of 13.22 ha to the north, Phase 7, and Phase 8 including an industrial land parcel of 3.19 ha to the south. All watermain connections from the S1 Area to the existing municipal network will be constructed as part of Phase 6, with the subsequent phases and future industrial lands extending from Phase 6.

Accordingly, the analysis and results in this Section are structured to reflect the cumulative staging of development:

- Phase 6 + Northern Industrial Parcel
- Phase 6 + Northern Industrial Parcel + Phase 7
- Phase 6 + Northern Industrial Parcel + Phase 7 + Phase 8 + Southern Industrial Parcel

The proposed connection at Kilbirnie Drive will extend from Quinn’s Pointe Stage 5, which has not yet been constructed but is planned to be completed prior to advancement of the S1 Area. Accordingly, the analysis and results incorporate the units from Quinn’s Pointe Stage 5 (herein referred to as “Stage 5”).

5.2.3 Domestic Water Demands

The water demands calculated for the S1 Area reflect the unit count and land-use areas shown on the Concept Plan (Appendix D).

System level parameters (Table 29) were provided by the City of Ottawa at the onset of this project given that the population of the S1 Area exceeds 3,000 (refer to Appendix J).

The maximum day demand shown in the table below is the sum of the average day demand, the water loss per connection and the outdoor water demand. The peak hour peaking factors shown below were provided by the City.

Table 29: Theoretical Water Consumption Rate

Land Use Type	Consumption Rate (L/cap/day)	Avg. Demand (L/unit/day)	Water Loss per Connection (L/unit/day)	Outdoor Water Demand (L/unit/day)	Max Day Demand (L/unit/day)	Peak Hour Demand
Single Family Homes @ 3.4 ppu	180	612	80	700	1,392	2.1 x Max
Executive and Avenue Towns @ 2.7 ppu	198	535	80	350	965	2.1 x Max
EMP (L/ha/day)	17,000	N/A	N/A	N/A	1.5 x Avg	1.8 x Max

When all the above parameters are applied to the S1 Area along with an assumed constant demand of 4 L/s for the park block, the following water demands were calculated as shown in the detailed water demand spreadsheet in Appendix J.

Table 30: S1 Area Water Demands

Phasing Scenario	Average Day Demand (L/s)	Maximum Day Demand (L/s)	Peak Hour Demand (L/s)
Phase 6	13.65	21.00	33.23
Phase 6, 7	15.46	24.00	39.27
Phase 6, 7, 8	18.11	28.53	48.24

*Note all scenarios include Stage 5.

5.2.4 Required Fire Flow

Based on the City's Design Guidelines, municipal watermains shall be designed to meet fire flow requirements estimated based on the Fire Underwriters Survey (FUS) method. To evaluate

the proposed water distribution system, a maximum fire flow of 13,000 L/min (217 L/s), based on the previous MSS Addendum, was targeted in the system for each phasing scenario shown in Table 30. A lesser fire flow of 10,000 L/min (167 L/s) was also assessed based on the City's capped fire flow requirement for single family homes and row townhouses that achieve adequate rear yard spacing.

5.2.5 Internal Water Servicing

Several 300 mm diameter feedermains are being proposed within the S1 Area. These trunk watermain locations have been determined based on the existing watermains surrounding the S1 Area as well as the Concept Plan and hydraulic requirements. The following trunk watermains are proposed, as illustrated on the Master Watermain Drawing (MWM in Appendix K):

- 300 mm diameter watermain westerly extension on Kilbirnie Drive.
- 300 mm diameter watermain westerly extension on Moyard Drive with 300 mm diameter watermain upgrade (±40m) on Moyard Drive west of Lynn Coulter Street.
- 300 mm diameter watermain westerly extension on Cappamore Drive.
- 300 mm diameter watermain southerly extension on Elevation Road.
- 300 mm diameter watermain westerly extension on Barnsdale Road.
- 200 mm or 300 mm diameter watermains at the west side of the S1 Area to provide looping between the extended watermains, including through the Industrial Lands, such to avoid the creation of dead-end feedermains.

5.2.6 Boundary Conditions

At the onset of this Study, boundary conditions were requested from the City for the existing pressure zone configuration and for the future South Urban Community (SUC) pressure zone reconfiguration. As the future SUC pressure zone reconfiguration is not expected to be completed until 2027, this Study analyzes results for both the existing and future pressure zones.

The boundary conditions received from the City (Appendix J) include connections to the existing watermains at Moyard Drive, Kilbirnie Drive, Obsidian Street, Elevation Road, Cappamore Drive, and Barnsdale Road. Boundary conditions were requested with and without a connection to Barnsdale Road as well as for the different phasing scenarios shown in Table 30. Although the boundary conditions indicate a marginal pressure increase with the Barnsdale Road connection, it is recommended that this looped connection be constructed for redundancy purposes given that the trunk sanitary sewer will also be extended westerly along this ROW. Thus, this Study only assesses the water servicing with the Barnsdale Road connection.

Boundary conditions received on November 24, 2025, were used for Phase 6 and Phase 6-7 scenarios and boundary conditions received on August 25, 2025, were used for the Phase 6-8 buildout scenario. It is noted that the current boundary conditions (received November 24, 2025) are generally reduced in pressure as compared to those presented in the previous studies carried out for these lands. This is attributed to the City's recent updates to their hydraulic water model which included updates to the pump controls at Barrhaven Pumping Station and updates to all water demands throughout the model, especially in neighbouring areas.

5.3 Water Servicing Analysis

The Hydraulic Network Analysis (HNA) was conducted using a model in WaterCAD® with a series of trunk watermains with a nominal diameter of 300 mm (modelled with an internal diameter of 297 mm) and 200 mm (modelled with an internal diameter of 204 mm). The 300 mm and 200 mm diameter watermains use a Hazen-Williams roughness coefficient (C-factor) of 120 and 110, respectively, per City Design Guidelines. A model schematic is presented in Appendix J that shows the proposed street centreline elevations and watermain sizing and layout within the S1 Area. The modelled watermain configuration follows the Master Watermain Drawing (MWM in Appendix K). The HNA encompassed system performance under three key scenarios: maximum hydraulic grade line (HGL) conditions, peak hour demand conditions, and maximum day demand plus fire flow conditions. These scenarios were assessed under both existing and future conditions (i.e., without and with the pressure zone reconfiguration). The model result schematics are presented in Appendix J.

The model results are presented for the phasing as follows:

- **Phase 6** = Phase 6 + Northern Industrial Parcel
- **Phase 7** = Phase 6 + Northern Industrial Parcel + Phase 7
- **Phase 8** = Phase 6 + Northern Industrial Parcel + Phase 7 + Phase 8 + Southern Industrial Parcel

5.3.1 Maximum HGL

The maximum HGL simulation was assessed to confirm that system pressures are expected to adhere to the maximum pressure constraint of 552 kPa (80 psi). This simulation was carried out assuming no demands, which is a conservative approach.

5.3.1.1 Existing Conditions

Table 31 below shows the pressure ranges for each phase scenario.

Table 31: Model Results – Maximum HGL Existing Conditions

Phase	Minimum Pressure	Maximum Pressure
Phase 6	443 kPa (59.9 psi)	533 kPa (77.3 psi)
Phase 7	436 kPa (61.5 psi)	527 kPa (76.4 psi)
Phase 8	424 kPa (59.8 psi)	515 kPa (74.7 psi)

Simulations for Phases 6, 7 and 8 result in pressures that are below the maximum allowable system pressure of 552 kPa (80 psi). Accordingly, each phase scenario satisfies the applicable pressure requirements.

5.3.1.2 Future Conditions

Table 32 below shows the pressure ranges for each phase scenario.

Table 32: Model Results – Maximum HGL Future Conditions

Phase	Minimum Pressure	Maximum Pressure
Phase 6	366 kPa (53.1 psi)	456 kPa (66.1psi)
Phase 7	366 kPa (53.1 psi)	456 kPa (66.1 psi)
Phase 8	362 kPa (52.5 psi)	452 kPa (65.6 psi)

Simulations for Phases 6, 7 and 8 result in pressures that are below the maximum allowable system pressure of 552 kPa (80 psi). Accordingly, each phase scenario satisfies the applicable pressure requirements.

5.3.2 Peak Hour

The peak hour simulation was assessed to confirm that system pressures generally comply with the normal operating conditions' minimum pressure constraint of 275 kPa (40 psi). This simulation was carried out by applying the peak hour demands in the model as summarized in Appendix J.

5.3.2.1 Existing Conditions

Table 33 below shows the pressure ranges for each phase scenario.

Table 33: Model Results – Peak Hour Existing Conditions

Phase	Minimum Pressure	Maximum Pressure (kPa)
Phase 6	289 kPa (41.9 psi)	380 kPa (55.1 psi)
Phase 7	260 kPa (37.7 psi)	350 kPa (50.8 psi)
Phase 8	282 kPa (40.9 psi)	373 kPa (54.1 psi)

Under Phase 6 and Phase 8, the pressures under peak hour conditions exceed the minimum pressure requirements.

Under Phase 7, the lowest system pressures occur at the east end of the study area (Appendix J) and along Kilbirnie Drive. Although these pressures fall below the minimum recommended pressure of 275 kPa for normal operating conditions, they are primarily attributable to local topographic high points rather than excessive headlosses within the watermain network. Under the future pressure zone reconfiguration, pressures improve along both the east end of the study area and Kilbirnie Drive, as presented next in section 5.3.2.2. Furthermore, the pressure zone modification will quite possibly occur prior to the construction of Phase 7. While pressures along Kilbirnie Drive during Phase 7 are marginally below guideline values for normal operating conditions, the latest City of Ottawa Design Guidelines do not explicitly define minimum pressures under peak hour conditions. This assessment will be refined at the detailed design stage when more definitive centreline elevation data becomes available.

5.3.2.2 Future Conditions

Table 34 below shows the pressure ranges for each phase scenario.

Table 34: Model Results – Peak Hour Future Conditions

Phase	Minimum Pressure	Maximum Pressure
Phase 6	285 kPa (41.3psi)	376 kPa (54.5 psi)
Phase 7	282 kPa (40.9 psi)	373 kPa (54.1 psi)
Phase 8	274 kPa (39.7 psi)	365 kPa (52.9 psi)

All modeled phase scenarios result in pressures that exceed the maximum allowable system pressure of 275 kPa (40 psi). Accordingly, each phase scenario satisfies the applicable pressure requirements.

5.3.3 Maximum Day plus Fire Flow

To ensure adequate fire protection, a maximum day demand was simulated with a fire flow along the proposed watermains within the S1 Area. As per Section 5.2.4, a fire flow of 10,000 L/min (167 L/s) and 13,000 L/min (217 L/s) was used in this analysis and assessed under existing and future pressure zone configurations.

5.3.3.1 Existing Conditions Fire Flow (167 L/s)

Under existing pressure zone conditions, for Phases 6, 7 and 8, the proposed watermain network is expected to be capable of delivering fire flows of 167 L/s during a maximum day demand.

5.3.3.2 Future Conditions Fire Flow (167 L/s)

Under future pressure zone conditions, for Phases 6, 7 and 8, the proposed watermain network is expected to be capable of delivering fire flows of 167 L/s during a maximum day demand.

5.3.3.3 Existing Conditions Fire Flow (217 L/s)

Under existing pressure zone conditions, for the proposed watermain network for Phase 6, 7 and 8, the network is generally expected to be capable of delivering fire flows of 217 L/s during maximum day demand. Under existing conditions simulations, nodes J-90 and J-34 along the woodlot easement and node J-48 on Kilbirnie Drive are unable to provide 217 L/s.

The lower available fire flow at this node can be attributed to the higher topography in this localized area and the headlosses along the watermains. Currently, on Street 5 there are no residential units along this section of watermain which require 217 L/s. Along Kilbirnie Drive, specifically at J-48, there are no residential units along this section of watermain. This portion of the site will be dedicated to light industrial uses. The required fire flow for the industrial block will be assessed at the detailed design stage for its site plan. It is noted that the available fire flow at these nodes improve with the future pressure zone reconfiguration as discussed in the next section.

5.3.3.4 Future Conditions Fire Flow (217 L/s)

Under future pressure zone conditions, for the proposed watermain network for Phase 6, 7 and 8, the network is generally expected to be capable of delivering fire flows of 217 L/s during

maximum day demand. Under future pressure zone conditions simulations, nodes J-90 and J-34 along the woodlot easement are unable to provide 217 L/s.

Currently, there are no residential units requiring 217 L/s along these sections of watermain. It is noted that the available fire flow at this node does improve with the reconfiguration of the future pressure zone. The lower available fire flow at this node can be attributed to the higher topography in this localized area and the headlosses along the watermains.

5.4 Water Summary and Recommendations

The proposed watermain trunk servicing within the S1 Area is shown on the Master Watermain Drawing (MWM in Appendix K). Water demands were calculated for the S1 Area using system level parameters provided by the City of Ottawa. A maximum fire flow target of 10,000 L/min (167 L/s) and 13,000 L/min (217 L/s) was used in this Addendum. Based on the boundary conditions provided by the City and the HNA presented herein, the proposed trunk watermains are generally expected to provide adequate water supply to the S1 Area.

6.0 Impact and Mitigation

6.1 Design, Construction and Operation

The analyses summarized in Sections 3.0 to 5.0 confirm that the preferred servicing strategy for the S1 Area is the extension of existing municipal services from the Quinn's Pointe and Ridge Subdivisions. The recommended servicing framework is illustrated on Drawings KS1, MG1, MST, MSAN, MWM, POND, D1, and D2.

The evaluation process of servicing strategies followed as part of the BSUEA MSS was extended to the S1 Area which had included an assessment of several indicators related to design, construction and operation, social, natural, and economic factors. This Addendum also reviewed both infiltration and filtration-type LID solutions as part of a simplified screening process which identified the preferred LID solutions. The impacts of the preferred servicing strategy on the S1 Area and the mitigation required are outlined in this section.

6.1.1 Storm and Stormwater Management Servicing

The preferred storm sewer and stormwater management servicing strategy for the S1 Area is based on a two-part approach, consisting of both infiltration and filtration measures:

- The infiltration-based solution builds upon the preferred servicing strategy identified in the 2018 BSUEA Master Servicing Study and includes: (i) the implementation of an Etobicoke Exfiltration System (EES) to promote recharge of the overburden aquifer, and (ii) infiltration of rooftop runoff through subsurface infiltration systems located on private properties.
- The filtration-based solution adopts a treatment train approach comprising a filtration dry pond supplemented with a mechanically treated device (MTD) to provide pre-treatment. This solution is proposed to service areas characterized by high groundwater conditions and areas where runoff quality may be influenced by roadway de-icing salts, such as collector roads.

With respect to the EES, one of the earliest known applications in Ontario was implemented in the former City of Etobicoke in 1993 as part of a retrofit project. While EES installations require enhanced inspection relative to conventional storm sewers, over approximately three decades of operation they have demonstrated reliable performance and maintenance requirements comparable to traditional systems. As part of the 2018 BSUEA MSS, several technical deliverables were prepared to support the acceptance of the EES; these documents are included in in Appendix C of this Addendum.

Prior to completion of the 2018 BSUEA MSS, the City confirmed that multiple EES installations form part of its existing municipally owned infrastructure. Since that time, EES has also been implemented within Quinn's Pointe Stages 2 through 4. Monitoring of the existing system indicates that it is operating in accordance with its design intent; however, elevated groundwater levels have the potential to limit system performance, as discussed in Section 3.7.

The preferred filtration-based servicing strategy consists of a filtration dry pond supplemented by an MTD for pre-treatment. This approach has been implemented elsewhere in Ontario and has been accepted by the City as a future municipally owned stormwater management facility.

The storm sewer and stormwater management servicing strategy detailed in this Addendum provides the following benefits:

- Preservation of the overall pre-development infiltration regime (water budget).
- Preservation of the baseflow characteristics.
- Mitigate adverse impacts (water quality) on the esker by means of implementing an filtration LID solution for the high-risk areas and areas where runoff will be impacted by chlorides.
- Reduce post-development peak flows, which in turn, will prevent increases in flood potential downstream.
- Protect downstream water quality by infiltrating or filtrating the first flush (22 mm storm) of the frequent storms, for parts of the Study Area where proper separation exists between the invert of the EES and groundwater levels.
- The servicing strategies meet the requirements of the CLI-ECA where the proposed solutions were developed based on the hierarchy described in Appendix A as follows:

    - ✓ Prioritize infiltration servicing solutions to the maximum extent while accounting for constraints.
    - ✓ Prioritize filtration servicing solutions to the maximum extent.

Since both types of solutions have been maximized, traditional stormwater management works such as a wet pond are not required nor recommended in this Addendum.

6.1.2 Sanitary Servicing

Sanitary servicing of the S1 Area has been described in greater detail in Section 4.0. Wastewater servicing will be achieved via extensions of the existing wastewater collection system. Consequently, there is no need for additional infrastructure to increase downstream conveyance capacity or to implement pumping to achieve gravity connections. In terms of operation, the extension of the gravity systems within the S1 Area will require standard operation and maintenance as for similar systems within the City.

6.1.3 Water Servicing

Water servicing of the S1 Area has been described in greater detail in Section 5.0. Watermain servicing will be achieved via extensions of the existing and planned trunk watermains and supplemented by local watermains. Consequently, there is no need for additional infrastructure to increase capacity or to implement pumping systems for servicing higher elevations.

There is an imminent pressure zone reconfiguration that is envisioned about the same time as the initial stage of the S1 Area will be made operational. The pressure characteristics was simulated and discussed in greater details in Section 5.0. In terms of operation, the extension of trunk watermains within the S1 Area will require standard operation and maintenance as for similar systems within the City.

7.0 Trunk Storm and Sanitary Sewers and Watermains

Sections 3.0, 4.0 and 5.0 documented the technical analyses that were carried out in support of trunk infrastructure sizing within the S1 Area. None of the trunk infrastructure identified will be subject to any additional Class EA review nor Approval.

Given that the BSUEA MSS reviewed several servicing alternatives in accordance with the Class EA, these solutions were extended to this undertaking. Screening of infiltration and filtration servicing solutions were investigated and evaluated as part of a screening process, consistent with municipal Class EA. Linear infrastructure proposed as part of this Addendum is as follows:

7.1 Stormwater Management and Servicing Projects

Several trunk sewers of various diameters are proposed to service the S1 Area, as illustrated on (Drawing MST). The key stormwater management components include the following:

- Trunk storm sewers along future Cappamore Drive, extending from the western limit near the southern Industrial Lands at Manhole STMH556 to the storm inlet at the dry pond (Manhole STMH600).
- Trunk storm sewers along Elevation Road, extending from Kilbirnie Drive at Manhole STMH513 through the pre-treatment device located along Street No. 15 to a flow-splitting manhole (labelled “Overflow”) within Block 61, discharging to either Manhole STMH500A or STMH500.
- A pre-treatment mechanically treated device (MTD; Defender Model FD-8HC), located south of Manhole STMH502 near the western boundary of Block 61.
- A filtration dry pond with inlet at Manhole STMH500A, situated near the future intersection of Cappamore Drive and Elevation Road.
- A flow-splitter manhole, labelled “Overflow,” located east of the proposed MTD.
- An end-of-pipe dry pond encompassing the filtration dry pond, with dual inlets at Manholes STMH500 and STMH600.
- A network of local storm sewers of varying sizes servicing residential and industrial lands within the S1 Area.
- The existing 900 mm diameter storm sewer outlet and outlet control structure near the southeast corner of Block 61 will be retained. The structure will be retrofitted with low- and high-level orifices sized in accordance with the criteria summarized in Table 13 (above).
- On-site storage facilities within both Industrial Blocks, designed to detain the 100-year design storm onsite while releasing flows in accordance with the available minor system capacity.
- Stormwater quality control measures within both Industrial Blocks, to be designed at the Site Plan stage to meet applicable water quality control requirements in effect at the time of approval.
- Implementation of an Etobicoke Exfiltration System (EES) along local roads, with a minimum 1.0 m separation from seasonally high groundwater levels. The EES is proposed within Areas 1A and 1B, as shown on (Figure 9).

7.2 Sanitary Servicing Projects

Several trunk sanitary sewers are proposed to service the S1 Area, as illustrated on Drawing MSAN). The proposed trunk sanitary sewer alignments include the following:

- Along Street No. 15, extending from the future Cappamore Drive extension at Manhole SAMH703 to Barnsdale Road at Manhole SAMH701.
- Along the Barnsdale Road right-of-way, extending from Manhole SAMH701 to the existing stub connection along Barnsdale Road near Sanitary Sewer Access SAEX04 within the Quinn's Pointe Subdivision.

7.3 Water Servicing Projects

Several 305 mm diameter feedermain extensions are being proposed, along the following roadways:

- Future Kilbirnie Drive extension, from the eastern boundary of the existing CDP limit to Borrisokane Road.
- Future Cappamore Drive extension, from the eastern boundary of the existing CDP limit to a point westerly to service the southern portion of the Industrial Lands.
- Future Elevation Road extension, from the northern boundary of the existing CDP limit to future Cappamore Drive extension, and southerly along Street No. 15 to Barnsdale Road.
- Future Moyard Drive extension from the eastern limit of the CDP to Street No. 5, and southerly to the Cappamore Drive extension.
- Conceptual watermain loops; one within the northern and one within the southern portion in the Industrial Lands.

8.0 Regulatory Approval Requirements and Development Applications

City Of Ottawa

This Addendum was prepared as an extension to the 2018 BSUEA MSS which was prepared as an Environmental Assessment Master Plan (i.e., Master Servicing Study). As such, this Addendum will require a technical review by several groups at the city of Ottawa. Ultimately, this Environmental Assessment Master Plan will require approvals under the *Planning Act*.

Given that this Addendum was prepared as an extension to the BSUEA MSS (2018) where several servicing strategies were analyzed under the Municipal Class Environmental Assessment, the proposed servicing strategies presented herein were developed in accordance with the planning principles of the Class Environmental Assessment. As previously noted, a screening process was carried out to assess various LID solutions with the preferred strategy scored the highest.

With the S1 Area being the last growth area in this quadrant bound by Highway 416 and Barnsdale Road, the servicing strategies for both wastewater and water are limited, and consequently, servicing is based on the capacity of linear infrastructure bounding the Site.

Ministry of the Environment, Conservation and Parks

Servicing strategies evaluated herein and in the 2018 BSUEA MSS were analyzed under the Municipal Class Environmental Assessment and are in accordance with the planning principles of the Class Environmental Assessment. Given that pre-authorized conditions of the Municipal CLI-ECA have been issued under the Environmental Protection Act, infrastructure meeting these conditions will fulfill the approval requirements of section 53 of the Ontario Water Resources Act for sewage works (sanitary and stormwater).

Section 7.0 documented trunk infrastructure supporting the urbanization of the S1 Area Concept Plan. All infrastructure listed in Section 7.1, 0 and 7.3 has been found to meet MECP's pre-authorized criteria under the CLI-ECA framework. Therefore, no additional approval from MECP is required.

Ontario Drainage Act

Any modifications to the hydrological regime or alteration to the serviced area of a municipal drain within the Mud Creek subwatershed, will require that it be documented in an Engineers Report, which is to be prepared by the Engineer of Record in accordance with the Ontario Drainage Act (Section 78, Chapter D.17, R.S.O. 1990).

RCI, the appointed Drainage Engineers for this project, will be coordinating this effort upon the approval of this Addendum. Given that a partial disconnection is being proposed, the process will be on-going in parallel and will not interfere with the completion of this MSS Addendum nor with the approval of the initial phase of the S1 Area.

Ministry of Transportation of Ontario

Although no formal approval is required, acceptance by the Ministry of Transportation of Ontario (MTO) of the proposed drainage alteration will be sought. A meeting was held on January 26, 2026, with representatives from MTO, to discuss the project as Borrisokane Road is part of MTO's Highway 416 right-of-way, and future interchange.

As noted in Section 3.3.2, there is a planned interchange in the southwest quadrant of the Barnsdale Road and Highway 416/Borrisokane Road intersection. A partial disconnection is being proposed which will alter the hydrological regime of the Borrisokane Road open ditch system. As per Section 3.13.4, the net impact of the drainage modification results in a reduction in both peak flows and runoff volumes released to this open ditch system.

Since the last version of the MSS, comments were issued by MTO on May 15, 2026, and a response to those comments submitted on May, 22, 2026 for MTO's review.

Rideau Valley Conservation

There is no formal approval of this MSS by the RVCA. However, the RVCA may review future development applications within the S1 Area to ensure that it is consistent with the conservation, development and management of natural resources. As part of this process, the RVCA will ensure that property and public are protected from hazards such as flooding and erosion. However, given the storm servicing strategy presented herein, flooding and erosion are not of concern since off-site discharges are less than those under existing conditions. Similar to the Existing Conditions Report (JLR, 2025), the City of Ottawa, to their discretion, will circulate the final version of this MSS to the RVCA as information.

Future Development Applications

Once this Addendum to the Environmental Assessment Master Plan (Master Servicing Study) is approved, it will also require council approval with the goal of lifting of the neighborhood overlay.

The alignment and sizing of infrastructure, as shown herein, is subject to change as part of *Planning Act* approvals and would be treated as minor changes to this MSS as part of Draft Plan approvals.

Subsequent development applications will be made in accordance with the policies outlined in the city of Ottawa Official Plan. The specific studies required under the development approval process are determined at the commencement of the process and provided at the pre-application consultation meeting with City staff. Specific studies may include:

- Geotechnical studies
- Community transportation and traffic studies
- Noise studies
- Site Servicing Study, including stormwater management
- Environmental Impact Studies.

Several of the above-noted Studies have already been completed as part of the Concept Plan Approval process and are unlikely require an update. However, Studies will be confirmed as part of the City of Ottawa pre-consultation process. A planning rationale outlining how the development meets the intent of the overarching plans for the area will also be required.

9.0 Financial Plans

9.1 Local Infrastructure and Development Charges

Local servicing infrastructure is anticipated to be funded by the developer through subdivision or site plan agreements, consistent with standard City of Ottawa development practices.

Infrastructure components that provide benefit beyond the subject lands or are required to support ultimate system build-out may be eligible for reimbursement through front-ending agreements, Development Charges (DC), or future City capital funding, subject to City approval. Based on the current DC By-law, oversizing payment will occur under the following:

- Sanitary sewers are greater or equal to 375 mm in diameter (> 80 L/s)
- Watermains are greater or equal to 406 mm diameter
- Storm Sewers are greater than or equal to 1800 mm diameter.

Based on current servicing and projects depicted on Drawings KS1, MST, MSAN, MWM as well as Drawings POND, D1 and D2, the following largest trunks are being proposed:

- 1800 mm diameter trunk storm sewers leading to STMH600.
- 375 mm diameter trunk sanitary sewers (flows < 80 L/s).
- 305 mm diameter trunk watermains.

Based on the above listed infrastructure, none of the linear infrastructure meets the oversizing policy of the city's Development Charges Act.

9.2 Cost Sharing and Opinion of Probable Costs

Minto is the sole landowner of the S1 Area. Therefore, there is no cost sharing of linear infrastructure envisioned as there are no arterials. However, oversizing cost to support the development of the park may apply.

Opinion of Probable Costs (OPC) will be completed by populating the city's Schedule B items for each of the stages of the development.

10.0 Infrastructure Phasing and Implementation

10.1 Adaptability

Once this Addendum to the MSS is approved and overlay lifted, construction of linear infrastructure can proceed following the typical Draft Plan of Subdivision process. It is, however, acknowledged that there may be changes prior to the construction being initiated/completed which would be documented as part of the subdivision approval process.

The alignment and sizing of infrastructure, as depicted on Drawings KS1, MST, MSAN and MWM and SWM projects depicted on Drawings POND, D1 and D2, is subject to change as part of *Planning Act* approvals and would be treated as minor changes to this Addendum.

10.2 Detailed Design

The objective of the MSS is to provide a high-level servicing solution, which can demonstrate that development is serviceable/feasible in accordance with municipal and provincial standards. Street-by-street detailed design and grading would still be required; however, this process would occur at the Plan of Subdivision or Site Plan applications stage.

10.3 Staging of Infrastructure

The development of the S1 Area will proceed from the eastern boundary of the Study Area, adjacent to the Quinn's Pointe Subdivision where infrastructure currently exists. Given that the Quinn's Pointe Stage 5 has yet been constructed, it could potentially, to the discretion of Minto, be combined with the initial phase of development within the S1 Area, referred to as Stage 6.

The intended phasing limits for the S1 Area is shown on the Concept Plan (Appendix D). As illustrated, the implementation of the S1 Area will proceed into three (3) successive phases; the initial phase noted as Stage 6, with two (2) subsequent phases noted as Stages 7 and 8. At this time, Minto plans to proceed with the development of the Industrial lands once Stages 6-8 have been completed.

Stage 6 would include the construction of the following roadways:

- Kilbirnie Drive extension, from the eastern limit of the S1 Area to the western edge of Block 63 (woodlot) near the eastern boundary of the Industrial Block.
- Elevation Road extension from Kilbirnie Drive extension to Cappamore Drive extension.
- The eastern leg of Street No 15, from Cappamore Drive to the southern limit adjacent to Barnsdale Road.
- Cappamore Drive extension, from the eastern limit of the S1 Area to Elevation Road extension near the northwestern corner of Block 61.
- Moyard Drive extension from the Industrial Lands pass Elevation Road up to the eastern limit of the S1 Area.
- Street No 1, Street No. 2, Street No. 3, and Street No.4.
- Street No. 5, Street No. 6, Street No. 7 (northern portion).

10.4 Construction of Infrastructure

Infrastructure, including storm, water and wastewater for Stage 6 will consist of the following:

- **Etobicoke Exfiltration System**: Street No 1, Street No. 2, Street No. 3, and Street No.4 as well as along Moyard Drive and Street No. 5, Street No. 6, Street No. 7.
- **Local and Trunk Storm sewers:** All storm sewers will be constructed along all roadways identified in Section 10.3
- **Watermains:** All local and trunk watermains will be constructed along the roadways identified in Section 10.3.
- **Sanitary Sewers:** All local and trunk sanitary sewers will be constructed along the roadways identified in Section 10.3.
- **End-of-Pipe Facility:** All the drainage components and associated infrastructure identified within or in the vicinity of Block 61, including the pre-treatment MTD, filtration dry pond and underlain subdrain system, and the dry pond will be constructed as part of the Stage 6 infrastructure work while the existing outlet structure and storm sewer will be maintained.

10.5 Monitoring

As the implementation of infrastructure proceeds with each of the phases of development, it is recommended that the on-going EES monitoring being conducted in Quinn's Pointe Subdivision be extended into the S1 Area once it has been completed in Quinn's Pointe Subdivision. At such time, monitors would be relocated initially in Stage 6 to gather additional data.

10.6 Implementation and Capacity Analysis

The initial phases of development can represent the most vulnerable period from a servicing and operational perspective, as only a portion of the ultimate infrastructure network is in place. During these early stages, temporary conditions such as reduced system redundancy, interim drainage patterns, and incomplete downstream works may exist. Accordingly, the proposed implementation strategy is intended to ensure that each phase of development functions independently and safely, with adequate servicing capacity and controls always provided until the full build-out of the infrastructure is achieved.

10.6.1.1 Storm Sewers and End-of-Pipe Facility

Storm sewers and ultimate end-of-pipe facility, including the MTD, by-pass manhole, filtration dry pond and dry pond including its existing outlet, are proposed to be constructed as part of Stage 6. Given that all drainage works in Stages 6 is intended to serve additional land, to account for future Stage 7, Stage 8, and Industria Lands, there are no capacity limitations for any of the storm sewers within Stage 6.

In terms of interim drainage conditions, the S1 Area is bounded by two (2) existing subdivisions, and by Barnsdale Road and Borrisokane Road. Therefore, there is no interim drainage conditions apart from the installation of temporary ditch inlets at the western and southern boundaries of Stage 6. The interim drainage condition and temporary infrastructure, including ICDs, will be developed as part of detailed design of Stage 6.

10.6.1.2 Sanitary Sewers

Trunk sanitary sewers that are planned to be constructed as part of Stage 6, are intended to serve additional land, to account for future Stage 7, Stage 8 and Industrial Lands, when constructed. Hence, there are no capacity limitations for any of the sanitary sewers in Stage 6.

Under the interim condition, temporary ICDs will be installed along any sanitary sewer that will service additional lands to limit wastewater flows that could be intercepted. Temporary flow restriction and details will be reviewed as part of detailed design of Stage 6.

10.6.1.3 Water Distribution Analysis

Water distribution systems are often vulnerable during the initial phase of a given development. As a result, the performance of each additional interim phase was evaluated under maximum HGL, peak hour and maximum day plus fire flow. It should be noted that as part of Phase 6, all connection points to the existing municipal distribution system will be utilized via trunk watermain extensions.

The Water HNA and modelling assessment presented in Section 5.3 demonstrates the following:

- Under Maximum HGL existing conditions, each phase is expected to adhere to the maximum pressure constraint of 552 kPa (80 psi).
- Under Maximum HGL future conditions, each phase is expected to adhere to the maximum pressure constraint of 552 kPa (80 psi).
- Under Peak Hour existing conditions, Phase 6 and Phase 8 are expected to adhere to the minimum pressure constraint of 275 kPa (40 psi). Phase 7 expects a few localized low-pressure areas, but these results are anticipated to be temporary if not trivial based on the pressure zone modification.
- Under Peak Hour future conditions, each phase is generally expected to adhere to the minimum pressure constraint of 275 kPa (40 psi).
- Under Maximum Day plus Fire Flow existing and future conditions, each phase is expected to provide 167 L/s at all nodes, and 217 L/s at most nodes. All required fire flows can be met with the proposed trunk watermains for each phase.

11.0 Conclusions

This Addendum to Extend Class EA Master Plan (MSS) prepared in 2018 for the BSUEA. The 2018 BSUEA MSS had reviewed a series of servicing strategies in accordance with the Class Environment Assessment (Class EA) and was completed in accordance with the Integrated Planning Process.

A simplified screening process was undertaken as documented in this Addendum. Infiltration LID and filtration LID alternatives were reviewed and documented in Section 3.10 and Section 3.11. The infiltration solution adopted as part of the 2018 BSUEA MSS was extended to the S1 Area while the proposed filtration LID solution that scored the highest has been recommended.

This Addendum has identified a recommended high-level servicing strategy for storm, wastewater and water servicing to support the proposed Concept Plan (Appendix D). The high-level servicing strategy developed herein demonstrates the feasibility of servicing the proposed S1 Area. The design criteria utilized to develop the servicing strategies shall be used to develop detailed design. It is anticipated that the detailed design to be carried out in the Plan of Subdivision application phase will be consistent with the MSS but will adapt for any alterations to the road and layout configurations. The MSS has been developed with this flexibility in the design.

Principal findings of this Addendum are set out below:

Storm Drainage and Stormwater Management

- The design of the storm drainage system has been undertaken using the dual-drainage approach. This Addendum has set out the design criteria for future draft plan and/or site plan applications for the S1 Area. The design criteria are consistent with current design standards.
- A Master Grading Plan was developed based on existing and proposed grades and utilized to develop the Master Storm Drainage Plan.
- The storm servicing solution developed for the S1 Area is being shown on the Key Servicing Plan and reflects the adopted servicing strategy.
- The infiltration servicing strategy was developed to the maximum extent while recognizing opportunities and constraints listed in Table A2 of the CLI-ECA. The strategy incorporates the Etobicoke Exfiltration System (EES), the recommended solution identified as part of the 2018 BSUEA MSS and supplemented by rooftop infiltration using sub-surface infiltration measures within the Industrial Lands.
- Both infiltration measures are to be sized to capture and infiltrate the 22 mm design storm event.
- Five (5) filtration-type servicing solutions were developed for the areas impacted by the constraints identified in the CLI-ECA,
- The five (5) filtration-type solutions were evaluated as part of a screening process which scored each LID solution against several minor and major criteria.
- The recommended filtration solution that scored the highest, Alternative 5, is being proposed.
- This LID solution is based on a treatment train approach where pre-treatment is being proposed by means of a MTD that is supplemented by a filtration dry pond, with bio-

retention media equipped with an underlain subdrain system surrounded by clear stone envelope, geotextile. Due to roadway salts, the filtration dry pond will be lined with a choked later to minimize migration of roadway salts to the aquifer.

- Given the same principle as an EES, the filtration dry pond was also sized to capture and filtrate the 4-hour 22 mm storm.
- Both proposed infiltration and filtration solutions were found to exceed the requirements of Table 3.2 of MECP's SWMPDM for an 80% TSS removal.
- The post-development water budget with proposed infiltration measures showed comparable infiltration identified under the pre-development water budget.
- The downstream storm boundary conditions or targeted flow allowances developed in the Addendum and were based on the design constraints of existing systems.
- A pre- and post-development analysis was completed to assess peak flows and runoff volumes along both Borrisokane Road (system owned by MTO) and Barnsdale Road open ditch systems as well as at the upper reach of the Thomas Baxter Municipal Drain. The analysis showed a reduction in both peak flows and runoff volumes along the open ditches noted above for all storm events. Hence, no adverse impacts were found along both open ditch systems.
- Simulation results along both Barnsdale Road and Thomas Baxter Municipal Drain have been assessed to not cause adverse impacts by the Team's biologist as reported in the Environmental Impact Statement for the S1 Lands.
- The trunk sewer network was conceptually sized based on the approved Concept Plan and modelled to ensure that the hydraulic grade line (HGL) elevations along the system maintained a 300 mm freeboard, which corresponds to 2 meters below proposed centreline elevations.
- The major overland system was simulated to assess ponding depths (static and dynamic) against the requirements of the SDG (December 2025) being that it shall not exceed 350 mm depth.
- Allowable minor system release rates were set at the required storm event, and future design should maintain the same release rate criteria.
- The stormwater management solution contained in Block 61 or proximity includes a pre-treatment MTD, a filtration dry pond which will be supplemented by an expanded dry pond surrounding this facility, replacing the existing spill-over area constructed as part of the Quinn's Pointe Subdivision.
- Post-development peak flows discharged in the existing 900 mm diameter storm outlet are maintained below those reported in the Site Servicing Report of the Quinn's Pointe Subdivisions.
- A significant area of the S1 Area is proposed to be disconnected from the Thomas Baxter Municipal Drain, which will result in a reduction in both peak flows and runoff volumes for all storm events. Once this Addendum is approved, it will be circulated to the appointed Drainage Engineer and used as part of an upcoming update to the Engineers Report.

Wastewater Servicing

- The residual capacities in the surrounding wastewater services were assessed to determine viable servicing outlets to accommodate wastewater flows from the S1 Area.
- Out of the potential connections, the extension of the existing Barnsdale Road 375 mm sanitary sewer was the only viable outlet having sufficient residual capacity and grade to accommodate wastewater flows from the S1 Area.

- The existing constructed wastewater system network is capable to accommodate servicing for the S1 Area.
- The MSS Addendum contains design criteria which are to be used for the S1 Area in future draft plan and site plan applications. The design criteria are consistent with current design standards.
- The proposed wastewater system layout has been conceptually sized based on the proposed Concept Plan.

Water Distribution

- The S1 Area can be serviced under current conditions with watermain extensions from the existing surrounding watermains within both the Quinn's Pointe and the Ridge Subdivisions.
- The S1 Area can also be serviced from the reconfigured pressure zone anticipated for implementation in 2027.
- The analysis confirmed that there are no upgrades to the existing nor to the planned distribution network identified in the latest Infrastructure Master Plan.
- Demand allocation for water supply servicing has been derived based on the Concept Plan and associated densities. The allocations were based on system level water consumption rates, and peaking factors provided by the City as the population for the S1 Area exceeds 3,000.
- Trunk watermain sizing has been carried out based on the Concept Plan and reflects trunk watermain extensions at the boundary of the S1 Area.
- This MSS has set design criteria which is to be used for the future draft plan and site plan applications for lands included in the S1 Area. The design criteria are consistent with current design standards.
- Individual potable water assessments will be carried out as part of the detailed design of the various phases of the subdivision as well as the Site Plans for the Industrial Lands using parameters consistent with the Water Distribution Design Guidelines (December 2025).

This report has been prepared by J.L. Richards & Associates Limited for Minto Communities Canada Inc.'s exclusive use. Its discussions and conclusions are summary in nature and cannot properly be used, interpreted or extended to other purposes without a detailed understanding and discussions with the client as to its mandated purpose, scope and limitations. 1. STANDARD CROSS-SECTIONS TO BE READ IN CONJUNCTION WITH THE GENERAL STANDARD CROSS-SECTION NOTES AND OTHER APPLICABLE CITY AND UTILITY PLANS AND DETAILS.
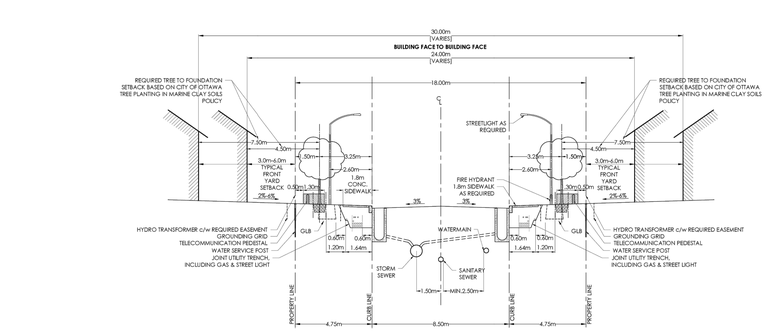
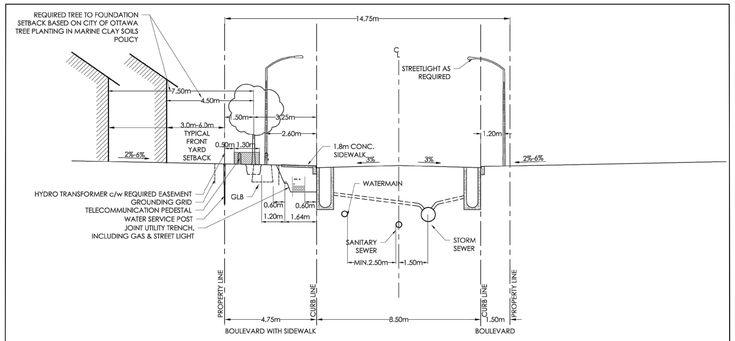
2. 18M RIGHT-OF-WAY NOT TO BE USED ON STREETS WITH BUS SERVICE.
3. CONCRETE CURBS TO BE CONSTRUCTED AS PER CITY OF OTTAWA STANDARD DETAILS.
4. TYPICAL FRONT YARD SETBACK IS TO BE CLEAR AND UNENCUMBERED OF ANY SUBSURFACE BUILDING ENCROACHMENTS.
5. FIRE HYDRANTS TO BE LOCATED ON THE WATERMAIN SIDE OF THE STREET.
6. CATCH BASINS TO BE PER CITY OF OTTAWA DETAIL S2.
7. GAS MAIN SHALL HAVE A MINIMUM OF 0.6M CLEARANCE FROM STRUCTURES (E.G. CATCH BASINS AND HYDRANTS) AND 1.2 M FROM TREE ROOT BALL.
8. STREETLIGHTS CAN BE LOCATED ON EITHER SIDE OF THE RIGHT-OF-WAY.
9. JOINT-USE UTILITY TRENCH (JUT) UNDER SIDEWALK AS PER DETAIL UDS0049, HELD BY HYDRO OTTAWA.
10. GRADE LEVEL BOX (GLB) AS DRAWN SHOWS GLB3660. EXACT LOCATION TO BE CONFIRMED.
11. THIS CROSS-SECTION CANNOT BE USED WHERE A CONCRETE ENCASED HYDROELECTRIC DUCT OR ANOTHER SEPARATE UTILITY DUCT IS REQUIRED.
12. TREE CLEARANCES TO HYDRO OTTAWA PLANT SHALL FOLLOW GCS0038
13. CLEARANCES SHOWN ARE MINIMUMS.



Ottawa	18.0m ROW CROSS SECTION
REV.DATE:	AUG. 2022
DWG. No.	ROW-18.0



NOTES:

1. STANDARD CROSS-SECTIONS TO BE READ IN CONJUNCTION WITH THE GENERAL STANDARD CROSS-SECTION NOTES AND OTHER APPLICABLE CITY AND UTILITY PLANS AND DETAILS
2. 14.75m RIGHT-OF-WAY NOT TO BE USED ON STREETS WITH BUS SERVICE
3. CONCRETE CURBS TO BE CONSTRUCTED AS PER CITY OF OTTAWA STANDARD DETAILS
4. TYPICAL FRONT YARD SETBACKS ARE TO BE CLEAR AND UNENCUMBERED OF ANY SUBSURFACE BUILDING ENCROACHMENTS
5. FIRE HYDRANTS SHALL BE LOCATED ON THE WATERMAIN SIDE OF THE STREET.
6. CATCH BASINS TO BE PER CITY OF OTTAWA DETAIL S2.
7. STREETLIGHTS MAY BE LOCATED ON EITHER SIDE OF THE RIGHT-OF-WAY.
8. GAS MAIN SHALL HAVE A MINIMUM OF 0.6m CLEARANCE FROM STRUCTURES (E.G. CATCH BASINS AND HYDRANTS) AND 1.2m FROM TREE ROOT BALL

10. GRADE LEVEL BOX (GLB) AS DRAWN SHOWS GLB3660. EXACT LOCATION TO BE CONFIRMED
11. THIS CROSS-SECTION CANNOT BE USED WHERE A CONCRETE ENCASED HYDROELECTRIC DUCT OR ANOTHER SEPARATE UTILITY DUCT IS REQUIRED
12. TREE CLEARANCES TO HYDRO OTTAWA PLANT SHALL FOLLOW GCS0038
13. BOULEVARD MAXIMUM SLOPE 1:3
14. NO RETAINING WALLS WITHIN 2.0m OF THE CURB LINE
15. CLEARANCES SHOWN ARE MINIMUMS

Ottawa	TITLE: 14.75m ROW CROSS SECTION
DATE:	AUG 2022
REV:	JULY 2024
DWG No:	ROW-14.75

NOTES:

1. THE STANDARD ROW CROSS SECTIONS INDICATE MINIMUM DIMENSIONS THAT ARE TO BE INCORPORATED INTO THE DESIGN OF ANY NEW DEVELOPMENTS INVOLVING NEW AND EXISTING STREETS. ANY VARIATIONS TO THE STANDARD ROW CROSS SECTIONS ARE SUBJECT TO THE INFRASTRUCTURE SERVICES DEVIATION PROCESS. CONTACT THE STANDARDS UNIT AT STANDARDSSECTION@OTTAWA.CA FOR MORE INFORMATION.
2. ALL DRAWINGS SHALL BE READ IN CONJUNCTION WITH APPLICABLE CITY STANDARDS, GUIDELINES, AND POLICES, INCLUDING COORDINATED UTILITY PLANS, GRADING PLANS AND LOCAL AREA PLANS. REFER ALSO TO UTILITY PARTNER STANDARD PLANT LOCATIONS.
3. ALL CROSS SECTIONS MAY BE SUBJECT TO SUBSEQUENT TRAFFIC CALMING MEASURES, TO BE DETERMINED THROUGH PLAN OF SUBDIVISION OR SEPARATE TRANSPORTATION STUDIES.
4. TYPICAL CROSS SECTION BOULEVARD WIDTH SHALL BE MAINTAINED WHEN CONSTRUCTING CUL-DE-SACS AND CORNER LOTS, REGARDLESS OF ROADWAY GEOMETRY.
5. WATERMAINS, WATER SERVICES, AND ASSOCIATED APPURTENANCES SHALL BE CONSTRUCTED PER THE WATER DESIGN GUIDELINES.
6. WATERMAIN AND HYDRANTS TO BE INSTALLED ON SOUTH AND EAST SIDE OF ROW, WHERE POSSIBLE.
7. SEWERS AND SEWER SERVICES SHALL BE CONSTRUCTED PER THE SEWER DESIGN GUIDELINES.
8. IN-ROAD CATCH BASINS SHALL ONLY BE USED ON RESIDENTIAL ROADS WITHOUT BUS TRAFFIC OR AS OTHERWISE DIRECTED BY THE SEWER DESIGN GUIDELINES.
9. BARRIER CURB SHALL BE USED ON ALL RESIDENTIAL ROADS WITH SINGLE FAMILY DWELLINGS. MOUNTABLE CURB MAY ONLY BE USED FOR AREAS WITH FREQUENT CURB-CUTS, SUCH AS TOWNHOME DEVELOPMENTS, WITH APPROVAL FROM THE CITY.
10. WATER AND SEWER SERVICES SHALL BE LAID AS PER CITY STANDARD DETAIL DRAWINGS, THE COORDINATED UTILITY PLAN, AND IN COORDINATION WITH ALL OTHER ELEMENTS IN THE ROW.
11. WHERE LOCATING WATER AND SEWER SERVICES UNDERNEATH LANDSCAPED AREAS WOULD PREVENT THE PLANTING OF A TREE, THEY MAY BE RUN UNDERNEATH THE DRIVEWAY OR OTHER HARDSCAPED AREAS.
12. MINIMUM 1.5 M CLEARANCE, AT-GRADE, TO BE MAINTAINED AROUND WATER SERVICE POST FROM TREE, TRANSFORMER, UTILITY PEDESTAL, TRAFFIC POLE, AND STREETLIGHT.
13. UTILITY PEDESTALS ARE TO BE GROUPED TOGETHER WITH THE HYDROELECTRIC TRANSFORMER, OR ON THE HOUSE SIDE OF THE UTILITY TRENCH.
14. STREETLIGHT CABLE SHALL BE LOCATED IN JOINT USE TRENCH (JUT). WHERE NO JUT EXISTS, ENSURE CLEARANCES TO TREE, HYDRANTS, AND WATER SERVICE POST.
15. TRAFFIC SIGNAL CABLE SHALL BE LOCATED IN THE JUT OR AT THE SAME OFFSET AS STREETLIGHT POLES IN A SEPARATE TRENCH.
16. TRAFFIC COMMUNICATIONS CABLE SHALL BE LOCATED IN THE JUT OR IN A TRENCH LOCATED AT THE SAME OFFSET AS THE STREETLIGHT POLES.
17. THE PREFERRED LOCATION FOR TRAFFIC HANDHOLES IS IN HARD SURFACES. WHEN HANDHOLES ARE PLACED IN THE BOULEVARD, A CONCRETE COLLAR SHALL BE PROVIDED.
18. THE DEVELOPER SHALL SUPPLY AND INSTALL DUCTS FOR UTILITY CROSSINGS AT INTERSECTIONS.
19. TREE PLACEMENT, NUMBER, AND SPECIES SHALL BE PER CITY POLICY, THE LANDSCAPE PLAN, COORDINATED-UTILITY-PLAN, AND THE DEVELOPMENT AGREEMENTS.
20. THE HYDRO TRANSFORMER BASE SHALL BE LOCATED A MINIMUM OF 2.0 M FROM THE DRIVEWAY EDGE.

Ottawa	TITLE: STANDARD NOTES ROAD ALLOWANCE

MEMO

Date: May 31, 2024

To: Robin van de Lande, City of Ottawa

From: Guy Forget P.Eng.

CC: John Bougadis M.A.Sc., P.Eng. (City of Ottawa), Curtiss Scarlett P.Eng. (Minto Communities – Canada)

Subject: S1 Urban Expansion Area– Terms of Reference

JLR No.: 26610-300

The S1 Urban Expansion Area (S1 UEA) will encompass ≈68 ha of proposed development located west of the established Quinn's Pointe Subdivision, south of the established Ridge Subdivision, north of Barnsdale Road and east of Borrisokane Road, within the Barrhaven South Area. Based on the latest Concept Plan (version 37), the eastern portion of the S1 UEA will consist of proposed residential development (formerly referred as the C1 Lands) owned by Minto Communities while the western portion will consist of proposed commercial development (formerly referred to the C2 Lands) owned Minto Greenfield (Barrhaven South). Minto Communities Inc. – Canada is overseeing the progress of the Approval process on behalf of both Minto Communities and Minto Greenfield (Barrhaven South).

The approval of the S1 UEA will follow the Concept Plan Approval (CPA) process given that the parcel is relatively small, and that ownership is virtually by one single Owner being Minto. Several deliverables will be prepared on behalf of Minto in support of the CPA process.

Master Servicing Process

The MSS for the S1 UEA will be completed in accordance with Appendix C of the Infrastructure Master Plan "Guideline for Preparing Terms of Reference for Master Servicing Study (June 2023)", which sets out the deliverables required.

Task 1: Terms of Reference

This Term of Reference (TOR) for the S1 UEA was prepared in response to the City request that a Master Servicing Study (MSS) Terms of Reference (TOR) be prepared for the S1 UEA in accordance with the "Appendix C: Guideline for Preparing Terms of Reference for a Master Servicing Study, June 2023" included in the Draft Infrastructure Master Plan.

Task 2: Existing Conditions Report (ECR)

The ECR will consist of the following:

- Review and Consolidation of background reports and information.
- Inventory of Water Crossings and Watershed Delineation
- Hydrological Modelling and Capacity Analysis of Conveyance Systems
- Water Budget Modelling
- Floodplain Mapping and Geomorphological Assessment
- Review Existing Conditions: Wastewater, Water and Storm Servicing
- Identify Constraints/Opportunities and Recharge/Discharge Areas
- Evaluation and Assessment of Storm Design Criteria and Objectives

- Assist Drainage Engineer with Hydrological Calculations for the Thomas Baxter Municipal Drain
- Prepare Existing Conditions Report

Several background reports will be reviewed including:

- Barrhaven South Urban Expansion Area MSS (JLR, 2018)
- MSS Addendum for the Barrhaven South Urban Expansion Area (January 5, 2021)
- Technical Memo – The Ridge & Drummond lands (DSEL, April 7, 2020)
- SWM Report, The Ridge (Brazeau lands), (JFSA, June 2020)
- Design Brief – The Ridge (Brazeau lands) (DSEL July 27th, 2020)
- Design Drawings – The Ridge (Brazeau Lands) (DSEL, 2020-09-25)
- Design Brief – The Ridge SWM Pond (DSEL/JFA, June 2020)
- Site Servicing Plan – 3713 Borrisokane Road (ABIC) (DSEL, December 2019)
- Technical Memo – 3713 Borrisokane (ABIC) (Dillon, November 4, 2020)

In addition to the above, this task will include the review of other information provided by Minto, the City of Ottawa and/or the Rideau Valley Conservation Authority (RVCA), including:

- Land Ownership with boundary information.
- Recent air photography.
- Topographical maps.
- LiDAR as provided by the City of Ottawa.
- Surficial geology from the province.
- Land use and vegetation.
- Topographical surveys (from Minto).
- Floodplain mapping at the boundary of the S1 UEA, if applicable.
- Other information compiled by the Team's Geotechnical/Hydrogeological Engineer, Biologist and Transportation Engineer.

Task 3: Future Development Condition

The approved ECR will identify constraints and opportunities which will encompass physical, environmental, as well as servicing constraints that will be determined from the inventory of existing linear infrastructure and potential outlets. At such time, a further review of topographical maps and surveys will be completed as well as the drainage patterns identified under existing conditions.

Given that this project will follow the Concept Plan Approval (CPA) process and that the latest Minto Concept Plan (version 37) has been reviewed and revised based on the city and Fotenn's input, a single Concept Plan will be analyzed once it has been updated/revised to reflect the ECR's findings.

Task 4: Servicing Design Constraints and Develop Design Criteria

Servicing constraints will be identified for the existing systems at or near the boundary of the S1 UEA.

- Review Servicing Constraints defined in BSUEA MSS and other Reports
- Coordinate and Liaise with Geotechnical Engineer and Hydrogeological Engineer
- Coordinate and Liaise with Biologist

Task 5: Servicing Alternatives for Wastewater, Water and Stormwater Management, Including Preparation of Master Grading

JLR will develop potential servicing alternatives, when applicable, for wastewater, water, storm and stormwater management recognizing constraints identified through the Existing Conditions Report and Concept Plan.

Task 6: Evaluation of Servicing Alternatives, when applicable, and Identification of Recommended Wastewater, Water and Stormwater Management Solution

High-level servicing alternatives developed as part of Task 5, will be evaluated to confirm their adequacy and to identify the recommended servicing alternative for wastewater, water and storm/stormwater.

Task 7: Review/Develop Implementation and Phasing Plans and Prepare Cost Estimate

Task 8: Approvals

Approvals by various groups at the city of Ottawa will be sought as part of this MSS as well as other stakeholders. Based on the previous BSUEA MSS, coordination with Minto's subconsultants was carried out throughout the ECR and MSS. As part of the BSUEA MSS, the following groups were consulted:

- CPT Members (as needed)
- City of Ottawa Economic Development Services
- City of Ottawa Transportation Planning
- City of Ottawa Parks Forestry & Stormwater Services
- City of Ottawa Transit Customer Services and Planning
- City of Ottawa Parks and Facilities Planning Services
- City of Ottawa Infrastructure Services
- City of Ottawa Planning Services
- City of Ottawa Right of Way Heritage & Urban Design Services
- Ottawa Public Health
- Rideau Valley Conservation
- Ministry of the Environment, Conservation and Parks
- Ottawa Carleton District School Board (OCDSB)
- Conseil des écoles publiques de l'Est de l'Ontario (CEPEO)

Executive Summary

Minto Communities Canada Inc. has retained several consultants to prepare a series of comprehensive documents to support the future development of the lands referred to as the Barrhaven South Phase 3 – S1 Area. The subject lands are herein referred to as the S1 Area. This Existing Conditions Report is submitted to the city in support of a Concept Design Plan, which will be implemented as an Amendment to the City of Ottawa Official Plan (OP).

J.L. Richards & Associates Limited (JLR) has been retained to prepare the Master Servicing Study (MSS) as part of the submission to outline water, wastewater, storm, and stormwater management servicing strategies for the S1 Area. In advance of preparing the MSS, an Existing Conditions Report is required to evaluate and assess existing water resources and servicing infrastructure within and around the S1 Area, and to identify constraints and opportunities.

The S1 Area is bounded by the existing Quinn's Pointe Subdivision to the east, by Barnsdale Road to the south, by the existing The Ridge Subdivision to the north, and by Borrisokane Road to the west. As such, the S1 Area is located immediately west and south of the current City of Ottawa Urban Boundary. The overall area is ≈71 ha which includes a retained woodlot and an artificial pond located at the Barnsdale Road and Borriokane Road intersection.

The subject site is an undeveloped mix of former agricultural land and forested areas spread generally across the site. Woodlots and pasture areas are present in the project site. The topography across the site has significant undulations, and, in general the lands slope down from the northern boundary to the southern boundary of the lands. Elevations of ≈112 m at the highest point near the northern boundary (adjacent to the Ridge Subdivision) and drops to ≈100 m at the lowest point, near Barnsdale Road. At the intersection of Borrisokane Road and Barnsdale Road, in the southwest corner of the site, there is an existing man-made pond that was excavated in the 1990's as displayed on the aerial on "geoOttawa".

For the purposes of defining the hydrology under the existing conditions of the S1 Area, the condition observed as part of the 2017 Existing Conditions Report for the BSUEA is consistent with the existing conditions noted as part of this undertaking. For the area encompassing the S1 Area assessed as part of the 2017 Existing Conditions Report, surface runoff is conveyed to the Mud Creek watershed, via the Thomas Baxter Municipal Drain and the Jock River watershed via a spill-over pond and rear yard catch basins and storm sewer system located within the Quinn's Pointe Subdivision and Greenbank Road.

It is our understanding that the investigations completed by Arcadis did not identify any formal conveyance channels within the S1 Area. The absence of channels or formal watercourses was confirmed by the LiDAR data. The absence of such waterways is generally indicative of areas exhibiting particularly low surface runoff potential. As a result, runoff generated from the site is carried as overland sheet flow to the natural low points at the culvert outlet locations.

Catchment areas within the S1 Area have been delineated based on LiDAR data compiled on behalf of the City of Ottawa, as well as any surface infrastructure such as roads, which tend to form a drainage path barrier, and culverts, where flow will concentrate into a point source. An understanding of the existing conditions in terms of capacity of the culverts and expected flow rates can be achieved from an accurate existing conditions hydrological model.

The SWMHYMO hydrological model, developed as part of the BSUEA, was maintained for the S1 Area. The model is a single event model for the purpose of estimating flood flows at the boundary control points of the site for storm events ranging from the 1:2-year and 1:100-year recurrence. The model was developed based on generally accepted standard hydrological parameters that fairly represent the land use, soil characteristics, types of flow paths, and topography. The simulated area included the S1 Area, as well as the lands up to the external boundary points: Cambrian Road, Borrisokane Road, and Barnsdale Road.

The SWMHYMO model results show relatively low flow rates at each of the culverts due to the high infiltration capability of the soils in the area and the low impervious ratio. In general, during larger and infrequent events, runoff will increase as the infiltration capability decreases due to saturation of the soils.

The water budget is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces, or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. The analysis of the water budget is often carried out to establish the baseline condition and assess any future changes in infiltration to subsurface water-bearing zones and, consequently, to surface runoff resulting from a significant land cover modification such as urbanization. It is also used to predict changes to the hydrological cycle that will result from urbanization of lands.

An understanding of the water budget within a given study area can be gained through the use of a continuous hydrological model. The PCSWMM software platform was used for this study, which included simplified groundwater and snowmelt modules that allowed the continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall, and snowmelt.

A long-term simulation was carried out for the site and was based on 20 years of hourly precipitation and temperature. Based on the long-term simulation results, infiltration accounts for approximately 34% of the total annual precipitation of 864 mm, while surface runoff accounts for approximately 7% on a yearly average.

A review of the existing and planned infrastructure (sanitary sewers, watermains, storm sewers, and stormwater management facilities) in the vicinity of the S1 Area was undertaken to assess available servicing opportunities and constraints within the subject lands.

The existing Greenbank Road trunk sanitary sewer was identified as the wastewater outlet for the existing Barrhaven South Community sanitary sewer system, which includes the Cambrian Road, River Mist Road, Barnsdale Road trunk sanitary sewers. Based on the theoretical peak flow calculations, the existing Barnsdale Road and Greenbank Road trunk sanitary sewers have sufficient capacity to accommodate the anticipated peak flows generated within the S1 Area.

Potable water will be provided to the S1 Area predominantly via potentially 300 mm diameter extensions from existing and planned feedermains located along the boundary with the Quinn's Pointe Subdivision and connections to the existing watermains within the Ridge Subdivision. There is a planned pressure zone reconfiguration that will occur in 2027 resulting in an expanded Zone 3C within areas previously identified as Pressure Zone BARR, including the Barrhaven

South Community, BSUEA and the future S1 Area. This future pressure zone is now being referred as Pressure Zone SUC.

Certain areas within the S1 Area might experience low pressures due to the high topography for a localized area near the Ridge Subdivision. However, this localized area has lower grades than the existing grades in the southern portion of the Ridge Subdivision. Hydraulic simulations will be required to be carried out as part of the upcoming MSS to determine if the localized area within the S1 Area will have pressures above the design criterion of 275 kPa (40 psi). Water servicing, watermain looping and sizing of the feedermains within the S1 Area will be determined during the MSS stage via a hydraulic network analysis (HNA).

The S1 Area is located on the edge of the current urban boundary and has existing or planned development on its eastern and northern boundary. The urban areas adjoining the S1 Area are currently serviced, or planned to be serviced, by SWMFs which were identified as part of the stormwater management strategy to service the Quinn's Pointe Subdivision to the east and the Ridge Subdivision to the north as identified in the BSUEA MSS (JLR, 2018), and in the BSUEA MSS Addendum (JLR, 2021) as summarized in this Report. There is an existing spill-over pond located within the S1 Area as it was identified to be required to support the Quinn's Pointe Stages 4 and 5 to prevent major overland flow from reaching New Realigned Greenbank Road. Given that no future additional flow allowance was to be incorporated in the Quinn's Pointe storm sewer system and spill-over dry pond, the existing residual capacities could be used as the dedicated capacity to accommodate the S1 Area.

The Hydrogeological Study undertaken by Paterson confirms that, in general, soils within the S1 Area have a moderate to high hydraulic conductivity with the highest hydraulic conductivity soils observed in the northwestern portion of the study area. Moderate hydraulic conductivity soil and shallow groundwater is encountered in the southern portion. Soils having the highest hydraulic conductivity are considered to act as a recharge zone for underlying aquifers and generally suitable for providing groundwater recharge and appropriate practices must be implemented to maximize the rate of infiltration. Based on fulfilling the objective of maintaining pre-development infiltration levels, storm servicing solutions incorporating infiltration measures will be reviewed and developed, when feasible, at the MSS level in order to achieve water balance.

1.0 Background

In 2016, Minto Communities Canada Inc. (Minto) and Mattamy Homes (Mattamy) retained a team of consultants to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA) Community Design Plan (CDP), which was subsequently implemented as an Amendment to the City of Ottawa Official Plan (OP). As part of this undertaking, J.L. Richards & Associates Limited (JLR) was retained to prepare a Master Servicing Study (MSS) to outline water, wastewater, storm, and stormwater management servicing strategies for the BSUEA. In advance of preparing the MSS, an Existing Conditions Report was prepared by JLR which evaluated and documented the existing water resources and servicing infrastructure in and around the BSUEA, and to identify constraints and opportunities which provided the baseline conditions of an Environmental Management Plan (EMP).

In 2018, following the approval of the BSUEA MSS, JLR was retained by Minto to proceed with detailed design of the three (3) of four (4) phases (Stages 2-4) of the BSUEA which are referred to Quinn's Pointe Stages 2-4 while Stage 5 is the last phase of development within the BSUEA.

In 2021, JLR was retained by Caivan Communities Inc. to prepare an MSS Addendum to "refresh" the 2018 MSS based on new preliminary engineering and detailed design engineering completed after 2018 to facilitate development of the former Aggregate Extraction Areas in the north part of the BSUEA.

In 2019, JLR was retained by Minto to prepare a Serviceability Study for the inclusion of several parcels located adjacent to the BSUEA. These parcels, previously referred to as the Barnsdale Expansion Lands, were mostly owned by Minto, and located either adjacent to the current Official Plan Urban Area, or in very close proximity of the Quinn's Pointe Subdivision (Stages 1-4). The 2019 Serviceability Study demonstrated that extensions to existing and proposed infrastructure could support the urbanization of these parcels. Given their location next to the Quinn's Pointe Subdivisions (existing and future), their urbanization was deemed a logical urban expansion in the Barrhaven South - Barnsdale Expansion Lands.

The high-level servicing solutions presented in the 2019 Serviceability Study for water, wastewater, storm and stormwater management were developed for the sole purpose of demonstrating the serviceability of the parcels. This Study was prepared to support an application to amend the Official Plan (OP) during the City of Ottawa (City) 5-year review of the OP.

Following a review of the 2019 Serviceability Study by the City, two (2) of the four (4) expansion parcels analyzed were approved to be included in the OP Urban Area. The approved expansion parcels consisted of the S1 Area, located west of the Quinn's Pointe Subdivision and north of Barnsdale Road, and the S2 Urban Expansion Area, located east of Greenbank Road and north of Barnsdale Road. These lands, now referred to as the Barrhaven South Phase 3 – S1 Area, are herein referred throughout this Existing Conditions Report as the S1 Area.

After several meeting between Minto and the City of Ottawa, it was understood that the S1 Area would not follow a full Community Design Plan process given that their urbanization was deemed a logical urban expansion of the current OP urban boundary.

Given that the S1 Area is a new urban area to be included in the OP urban boundary, the Concept Design Plan Amendment process will require that specific documents be prepared in accordance

with “Appendix C: Guideline for Preparing Terms of Reference for a Master Servicing Study, June 2023” which was included in the Draft Infrastructure Master Plan.

Based on this Guideline, a Table of Content and Terms of Reference was submitted to the City for their review. These documents will provide a road map for the preparation of an Existing Conditions Report and MSS. As such, the purpose of this Existing Conditions Report and subsequent MSS is aimed to support the Concept Plan and upcoming Draft Plan of Subdivision for S1 Area, which will be implemented as an Amendment to the City OP. The Terms of Reference is included in Appendix B1.

In advance of preparing the MSS, this Existing Conditions Report will evaluate and assess existing water resources and servicing infrastructure in and around the S1 Area, and to identify constraints and opportunities that will provide the baseline conditions of an Environmental Management Plan (EMP).

2.0 Study Area

2.1 Location

The S1 Area encompasses ≈71 ha of an undeveloped mix of former agricultural field and woodlots and a man-made excavated pond. It is bounded by Barnsdale Road to the south, by the existing and future Quinn’s Pointe Stage 4 and Stage 5 to the east, by Borrisokane Road to the west and by the former Brazeau Aggregate Extractions Area to the north, now a Caivan Greenbank Development. The S1 Area is located immediately west and south of the current City of Ottawa Urban Boundary as shown in Figure 2-1. The S1 Area is a logical development pattern, with improved phasing opportunities and more efficient connection to surrounding development and infrastructure.

2.2 Characteristics

As previously noted, the subject site is an undeveloped mix of former agricultural land and two (2) woodlots, one of which has been identified as being of significance.

The topography across the site has significant undulations, and, in general the lands slope down from the northern boundary to the southern boundary of the lands. Elevations of ≈112 m at the highest point near the northern boundary and drops to ≈100 m at the lowest point, near Barnsdale Road.

At the intersection of Borrisokane Road and Barnsdale Road, in the southwest corner of the site, there is an existing man-made pond that was excavated in the 1990’s as displayed on the aerial on “geoOttawa”.

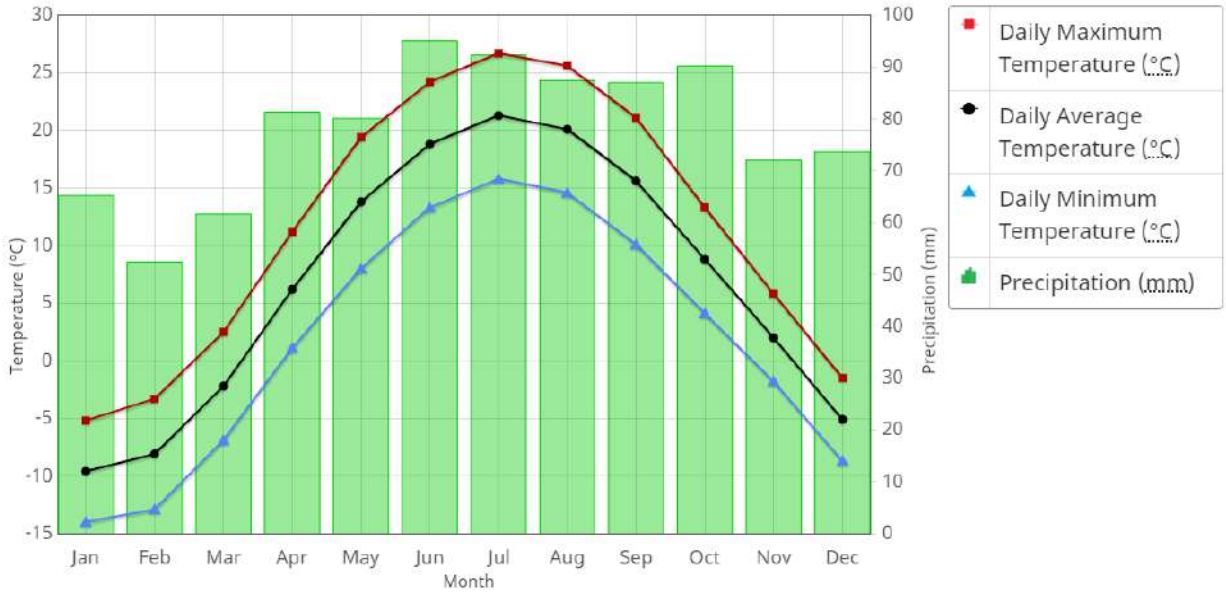
2.3 Climate

Environment Canada collects meteorological data at two (2) weather stations within the vicinity of the study area: the Ottawa CDA at the Experimental Farm (16 km to the northeast) and the Ottawa MacDonald Cartier International Airport (10 km to the northeast). The averages of the data collected at these two (2) stations provide some information on the climate expected in the study area (Figure 2-2).

The average temperature for the S1 Area varies between about -10°C in the winter and over 20°C in the summer. The daily maximum and minimum averages vary between 3.7 and 5.5 degrees from the average, with the greatest difference observed in the summer months. Evaporation is high in the summer, and negligible in the winter. Snowfall is highest during the December/January period. Generally, precipitation volumes are higher in the summer months, although the season variation is not as pronounced compared to temperature: the seasonal differences are usually no more than 40 mm and for three quarters (75%) of the year the variation in precipitation is no more than 20 mm.

Figure 2-2: Environment Canada, Ottawa Climate Normals (Ottawa City)



3.0 Background Documents

An exhaustive review of background documents and reports was completed as part of the BSUEA Existing Condition Report (JLR, 2017). At the time, the documents reviewed and summarized included subwatershed studies of the Jock River (covering the areas north of the site) and Mud Creek (covering the south of the site), and servicing strategies for the surrounding urban development lands northeast of the site. This review was summarized in four (4) categories and was included in the 2017 Existing Conditions Report (refer to Appendix B1 of 2017 Report).

The 2021 MSS Addendum reviewed and summarized new background information prepared for Caivan's "The Ridge Subdivision" (formerly Brazeau), the ABIC Lands and the future "Drummond Subdivision".

In August 2024, Design Reports were received from the city for the most recent developments in the Barrhaven South Area. These following documents have been gathered and reviewed as part of this Existing Conditions Report, including:

- The Ridge Phases 1 & 2 (Caivan Communities - formerly Brazeau)
- The Ridge Phases 3 & 4 (Caivan Communities – formerly Drummond)
- Half Moon Bay South Phase 1 to 5 and Phase 8 (Mattamy)
- The ABIC Commercial Lands
- Quinn's Pointe Stages 1 to 5 (Minto Communities)
- The Meadows Phase 1A, 1B and 2A (Tamarack Homes)
- The Meadows Phase 7 and 8 (Tamarack Homes)
- Half Moon Bay West Subdivision (Mattamy Homes)
- Barrhaven South Master Servicing Study (Stantec, October 12, 2017)
- Barrhaven South Master Servicing Study Appendices Volume 1 and 2 (Stantec, June 2007)
- Master Servicing Study Addendum Barrhaven South Urban Expansion Area (JLR, January 5, 2021).

Thus, the Master Sanitary Design Sheet included in Appendix B4 was updated based on the previous design sheet and integrated the above information.

4.0 Geology and Physiology

4.1 Surficial Geology

A Geotechnical Investigation was carried out by Paterson Group Inc. (Paterson) to assess general subsoil and groundwater conditions within the boundaries of the S1 Area and to provide geotechnical recommendations for the design of municipal services associated with the proposed development. The Report is entitled "Geotechnical Investigation Proposed Residential Development - Barrhaven South Expansion, Paterson Group Inc., March 25, 2024".

Based on Paterson's data gathering, the subsurface profile encountered for most of the test holes consisted of topsoil underlain by compact to very dense silty sand becoming silty sand to sandy silt with depth (Section 4.3 of Paterson's Report). The Report noted that the silty sand/sandy silt contained gravel, cobbles, and boulders at several test hole locations. A layer of stiff to very stiff brown silty clay with sand was encountered within the silty sand/sandy silt deposit at some test hole locations, predominately observed to be present within the northwest corner and central east portion of the site and at depths ranging between 0.3 m to 3.3 m with an approximate thickness of 0.4 to 3 m.

A field program, consisting of 9 boreholes and 18 monitoring wells, was carried out in the spring between April 11 and 18, 2022 and later in the fall between October 6 and 8, 2022. The data collected supplements the boreholes and monitoring wells established as part of the 2015 Existing Conditions Geotechnical Work which was also completed by Paterson.

The boreholes/monitoring well were advanced to depths ranging from 2.5 m to 12 m below existing ground surface. The test hole locations for the current investigation were distributed in a manner to provide general coverage of the S1 Area. It should also be noted that prior to 2015 investigations were also carried out in 2003 and 2011, which consisted of 27 test pits that were advanced to depths ranging from 2.7 m to 7.0 m.

4.2 Bedrock

Based on the available geological mapping, Paterson noted in their Report that the bedrock throughout the subject site consists of dolomite of the Oxford Formation with an overburden drift thickness of 15 m to 25 m.

4.3 Aquifer Systems and Groundwater

The Mud Creek Subwatershed Study (2015) has identified the area within the S1 Area as being part of the Mississippi-Rideau Source Protection Region (MRSPR) Significant Groundwater Recharge Area as depicted in Figure 8 of the 2015 Report. Based on the source protection atlas from the Ministry of the Environment, Conservation and Parks (MECP), all the S1 Area cover Highly Vulnerable Aquifers. Thus, site servicing developed as part of the upcoming Master Servicing Study will need to incorporate mitigation measures into the storm servicing strategy accounting for the delineated significant groundwater recharge area and account for any source water protection requirements of the Highly Vulnerable Aquifers.

5.0 Site Hydrology and Hydraulics

5.1 General

The 2017 Existing Conditions Report reviewed in detail the various sub-watersheds impacted by the BSUEA. At the time, it was determined via the review of the LiDAR and topographical survey along the boundary roadways that runoff from the BSUEA under pre-development conditions was tributary to three (3) sub-watersheds: the Jock River, Mud Creek via the Thomas Baxter Municipal Drain, and the Rideau River via the Hawkins Municipal Drain.

For the purposes of defining the hydrology under the existing conditions of the S1 Area, the condition observed as part of the 2017 Existing Conditions Report is considered consistent with the existing conditions noted at this time. It is anticipated that stormwater runoff from the S1 lands will be discharged via a new facility at the location of the existing overflow dry pond on the site, developed as part of the original BSUEA works. Since the design will not be dependent on the surrounding hydrologic existing conditions, and there have not been any changes to drainage connections for the S1 lands since 2017, the presentation of the 2017 existing conditions of the hydrology and hydraulics, other than the water balance and servicing connections, is considered sufficient.

For the area encompassing the S1 Area assessed under the 2017 existing conditions there are two (2) distinct sub-watersheds contributing to downstream receivers: the western part of the S1 Area is tributary to Mud Creek via one of the branches of the Thomas Baxter Municipal Drain; the remaining eastern part of the S1 Area, is tributary to the Jock River via the storm sewer system within the Quinn's Pointe Subdivision and Greenbank Road.

The area tributary to the above-noted sub-watersheds has been depicted in Figure 5-1. Based on the study area limits, approximately 2.7 ha is tributary to the Jock River (via Quinn's Pointe while an area of approximately 68 ha is tributary to Mud Creek. It is noted that although the Spence Branch of the Thomas Baxter Municipal Drain (shown at the bottom of Figure 5-2) is mapped by the City of Ottawa as Municipal Drain, it was not found during site observations. All flows appear to go to the Dynes Branch west of Borrisokane Road.

The investigations completed by Arcadis, the Team's biologist, did not identify any formal conveyance channels within the S1 Area. The absence of channels or formal watercourses was confirmed by the LiDAR data. The absence of such waterways is generally indicative of areas exhibiting particularly low surface runoff potential. As a result, runoff generated from the site is carried as overland sheet flow to the natural low points at the culvert outlet locations.

5.2 Water Crossings

A total of thirteen culvert crossings were inventoried as part of the 2017 Exiting Conditions for the BSUEA. Among these culverts, seven (7) culverts were inventoried at the boundary of the S1 Area, which can be grouped into the following two (2) categories:

- Boundary: There are four (4) culvert crossings along the Barnsdale Road boundary of the area being modelled, culvert Ids BDR. Of the four culverts, one (1), BDR-C4, forms the downstream boundary of the modeled area, where overland sheet flow forms a concentrated point flow external to the site.
- Internal to the model: There are three (3) culvert crossings that are internal to the area being modelled. These crossings currently provide conveyance across access routes to property and farmland along Borrisokane Road and have culvert Ids referenced as "CVR".

The inventoried crossings have been summarized in Table 5-1, below, while Figure 5-2 depicts the location of the culvert crossings along with the general site hydrology. It should be noted that none of the inventoried water crossings are within the S1 Area limits, except for CVR-C2 and CVR-C3, that are located along Borrisokane Road and adjacent to the man-made impoundment pond. Additionally, no documented culvert change was received nor did the "geoOttawa" platform indicate a new crossing. Therefore, all the culverts listed are unchanged since the assessment of existing conditions in 2017.

Table 5-1, above, summarizes the various culvert crossings within the S1 Area. As shown above, all the culverts are 500 mm in diameter or less except for CVR-C4 and BDR-C4, which are 1200 mm in diameter.

5.3 Watershed Delineation

Catchment areas within the S1 Area have been delineated based on LiDAR data compiled on behalf of the City of Ottawa, as well as any surface infrastructure such as roads, which tend to form a drainage path barrier, and culverts, where flow will concentrate into a point source. The delineated catchment areas are split by the two (2) watershed areas noted above: Jock River to the east via the Quinn's Pointe Subdivision systems, Mud Creek to the south via the Thomas Baxter Municipal Drain. The catchment areas are summarized in Table 5-2 and are shown in Figure 5-2. The delineation of the watersheds in 2017 was undertaken with the 2015 LiDAR provided at the time of the report.

Table 5-2: Subcatchment Summary

5.4 Hydrological Modelling

5.4.1 Model Parameters

An understanding of the existing conditions, in terms of expected flow rates and capacity of the culverts, is normally assessed with an existing conditions hydrological model. To simulate the hydrological response of a given area, a hydrologic model should, ideally be calibrated, to actual monitored flows to ensure a true representation of the physical characteristics of the catchment area during the recorded storm events. To determine flows to the culvert BDR-C4 on Barnsdale Road at the downstream end of the S1 Area draining to Mud Creek, via the Municipal Drain, the approved model developed as part of the 2017 BSUEA Existing Conditions Report was utilized as reflecting the existing conditions for the S1 Area.

The existing conditions model in 2017 was developed based on generally accepted standard hydrological parameters (per the OSDG, MTO Drainage Manual and SWMM5 Guide) that fairly represent the land use, soil characteristics, types of flow paths, and topography.

5.4.2 Storm Distribution

The hydrological response of the S1 Area and abutting lands was simulated under a 6-hour, 12-hour, and 24-hour SCS Type II storm distribution. The SCS Type II storm distribution was developed by the American Soil Conservation Service and is generally used for estimating flows in rural areas. The critical storm event under pre-development conditions, with the highest peak runoff, was found to occur under the 12-hour SCS Type II storm distribution.

5.5 Modelling Results

The subject site was modeled using the SCS Curve Number (CN) methodology to simulate runoff. The CN number is selected based on the soil types in the area and the land cover, which in this case is predominately rural in nature with either agricultural or woodlot classifications. The site consists of 'unimproved lands', which consist of lands that are undeveloped open space with no current use. This classification was also used for the quarry areas. Land uses for the model area are shown in Figure 5-3, while a summary of the hydrological parameters is shown in Table 5-3.

Table 5-3 - Model Parameter Summary

Drainage Area ID	Area (ha)	CN*	Initial Abstraction (mm)	Time to Peak (hrs)
A10	5.5	55	14.4	0.27
A11	15.2	55	14.4	1.27
A12	60.0	51	16.9	0.95
A13	24.6	52	16.2	0.5

The soil types in the area are predominately soils with high infiltration and low runoff potential, even when saturated. Soil types by geotechnical description are depicted in Figure 5-4.

The model schematic is contained in Appendix B2 which also includes a detailed description of all the model parameters, including Time to Peak, Initial Abstraction, etc. (refer to Appendix B2).

The pre-development simulation results from the 2017 modelling, predicting flows at each of the culverts for the critical storm event, are shown in Table 5-4, below. The estimated capacity and level of service of each culvert is also provided.

Table 5-4: Hydrological Simulation Results at Culvert Locations (12-hour SCS Type II storm)

Culvert ID	Flow (m^3/s) at culvert location for 1:25 yr	Flow (m^3/s) at culvert location for 1:50 yr	Flow (m^3/s) at culvert location for 1:100 yr	Estimated Culvert Capacity (m^3/s)	Estimated Level of Service (years)
CVR-C2	0.2	0.2	0.3	0.2	1:25
CVR-C3	0.2	0.3	0.4	0.3	1:50
CVR-C4	0.9	1.1	1.4	2.6	1:100
BDR-C1	0.1	0.1	0.2	0.2	1:100
BDR-C2	0.1	0.2	0.2	0.2	1:50
BDR-C3	0.2	0.2	0.3	0.5	1:100
BDR-C4	0.9	1.2	1.5	2.6	1:100
Total to Municipal Drain	1.1	1.3	1.6	N/A	N/A

The model results noted above show relatively low flow rates at each of the culverts, due to the high infiltration capability of the native soils in the area and the low impervious ratio. In general, during larger and infrequent events, runoff will increase as the infiltration capability decreases due to saturation of the soils.

Culvert BDR-C4 crosses the main boundary road of the S1 Area and was found to have a high estimated level of service (more than 1:100 years). Since Barnsdale Road is classified as an arterial or collector road, the culvert would be expected to have a higher level of service compared to the internal culverts to the site or under access roads south of Barnsdale Road.

5.6 Hydraulics and Floodplain Mapping

Similar to the findings included in the BSUEA Existing Conditions Report (JLR, 2017), there are no well-defined watercourses on-site as shown on the LiDAR which are significant enough to warrant a hydraulic analysis or to prepare floodplain mapping. Flow conveyance for most of the subject site occurs by means of overland sheet flow, and flow in small, intermittent swales/channels. The floodplain of the Jock River subwatershed extends close to the site but remains within the northwestern quadrant of the Cambrian Road / Borrisokane Road intersection (Figure 5-1). The floodplain of Mud Creek does not extend close to S1 Area.

6.0 Water Budget

The water budget of a given area is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces, or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. The analysis of the water budget is often carried out to establish the baseline condition and assess any future changes in infiltration to subsurface water-bearing zones and, consequently, to surface runoff resulting from a significant land cover modification such as urbanization. The analysis It is also used to predict changes to the hydrological cycle that will result from urbanization of lands. In simple terms, the general water budget assesses the change in water storage resulting from the difference in water inputs and outputs for a given area or watershed. To estimate the water budget, the following simplified equation is used:

$$P = ET + SW + GW + \Delta S$$

Where:

- P is precipitation;
- ET is evapotranspiration;
- SW is surface runoff;
- GW is groundwater; and
- ΔS is the difference in water storage.

As a fundamental requirement, the water budget developed for the existing conditions will be used as the baseline condition when assessing the effectiveness of any stormwater management (SWM) servicing strategies under the post-development condition Future SWM strategies should adhere to the recent provincial guidance from the MECP (MOECC) in their publication entitled “Expectation interpretation bulletin, February 2015”, as well as relevant provincial policy statement. In addition, the servicing of the site will require to adhere to the criteria for pre-authorized alteration to the City of Ottawa’s CLI-ECA (issued December 19, 2024), which has water recharge requirements. The 2024 Infrastructure Master Plan (IMP) and Official Plan has policies which require water balance assessments and runoff volume control targets to be assessed. One of the objectives of the upcoming Master Servicing Study for the S1 Area will be to develop a storm servicing strategy that will incorporate mitigation measures to minimize the water deficit to offset the potential impact of urbanization.

6.1 Continuous Modelling

An understanding of the water budget within a given study area can be gained using a continuous hydrological model. The Toronto and Region Conservation Authority (TRCA), in their publication entitled “Stormwater Management Criteria, August 2012”, recommend the use of a continuous model such as QUALHYMO or PCSWMM. A continuous simulation model is being implemented at this stage to facilitate assessment of implementation of infiltration processes integrated into the site development.

The PCSWMM model to be used for this study includes simplified groundwater and snowmelt modules that allow the continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall, and snowmelt. Due to its capabilities and versatility, the PCSWMM modeling tool will also be used to assess the

impact of development and effectiveness of the proposed Low Impact Development (LID) measures.

6.1.1 Infiltration Parameters

Saturated field hydraulic conductivity of the surficial soils for the S1 Area was measured in the field by Paterson during their site visits between May and October 2022. Field measurements of infiltration were by means of permeameter testing at depths between 0.5 m and 0.7 m below ground surface. Paterson have delineated six (6) zones of infiltration across the site varying in three (3) infiltration rate ranges. The infiltration rate ranges are from 30 to 50 mm/hour, 50 to 100 mm/hour and greater than 100 mm/hour, without application of any safety factor.

The median of each range has been applied as the representative infiltration rate and applied to the Horton Maximum Infiltration Rate in the model on a spatially weighted basis across the delineated subcatchments. Table 6-1, below, summarizes the various ranges of saturated field hydraulic conductivities and their corresponding range of maximum infiltration rates as well as the selected final infiltration coefficient used in the water budget model. In the previous BSUEA analysis, it was carried out using the minimum, median, and maximum values and the results indicated that there was negligible difference in the results within the range of infiltration values. The BSUEA simulation showed that only during the infrequent large peak rainfall events will infiltration be affected by the change in the parameter values. Therefore, the selection of the median value for the parameters for this analysis is suitable.

A decay constant, k, of 4.14 hr^{-1}, was used in the SWMM model to mimic the decreasing infiltration capacity of the soil over time during wet weather events.

It should be noted that since the water balance modelling was completed in 2017 for the BSUEA, the EPA SWMM 5.2 simulation engine was updated to allow seasonal adjustments to the infiltration capacity of soils over long term simulations. The adjustment to prevent infiltration during the winter period is consistent with the approach in the Thornthwaite Mather calculation method and is representative of frozen ground conditions present during the winter months. The extent of infiltration in a month has been prorated with the Environment Canada climate normals based on number of days with a minimum temperature below freezing as a general indication of likely infiltration. The infiltration monthly multipliers and days below freezing are provided in Table 6-2.

Table 6-1: Horton Coefficients for Water Budget Model

Range of Unfactored Infiltration Rates	Horton Maximum Infiltration Rate (mm/hr)	Estimated Soil Groupings (based on infiltration values)[1]	Horton Minimum Infiltration Rate (mm/hr)[1]	Selected Final Infiltration Coefficient (mm/hr)
30 - 50	40	Moist Loam Soils	3.8 - 7.6	3.8
50 - 100	75	Moist Loam soils	3.8 - 7.6	7.6
>100	100	Moist to Dry Sandy Soils	7.6 – 11.4	11.4

November	18.1	0.4
December	27.8	0.1

6.1.2 Precipitation and Evaporation

The water budget model was simulated under continuous mode using precipitation data from the Environment Canada weather stations at the Experimental Farm in Ottawa (approximately 15 km from the S1 Area). Twenty (20) years of hourly data, between April 19, 2004, and April 10, 2024, was used to undertake the water budget analysis. The average annual rainfall during this period was 864 mm, while maximum and minimum daily temperatures from the same weather stations and time period were also used.

The model undertakes evaporation calculations based on average monthly rates of evaporation (as reported by Environment Canada, refer to Section B2.3) and from the available standing water that is “trapped” in natural depressions within the subcatchment surfaces as a result of the initial abstraction depth.

6.1.3 Groundwater

The PCSWMM software platform analyzes groundwater flow for each of the simulated subcatchments independently. The model represents the subsurface region below a subcatchment as an unsaturated upper zone that lies above a lower saturated zone. The elevation of the lower saturated zone, the water table, varies in time depending on the rates of flow into and out of the lower saturated zone. The flow to the lower saturated zone is controlled by percolation, which is dictated by the soil characteristics, which is often represented by measured data. The upper unsaturated zone receives water via infiltration from surface runoff. Evapotranspiration occurs from the upper unsaturated zone; it can also occur from the lower saturated zone, depending on root depth. If the water table, or elevation of the lower saturated zone, reaches the surface level then all the soil becomes saturated, and infiltration will no longer occur.

For the purposes of modelling the project's water budget under existing condition, subcatchments were delineated by each hydrologic soils group (HSG) reflecting Paterson's characterization of the S1 Area as described in their Geotechnical/Hydrogeological Investigation. The soil parameters associated with each HSG are detailed in Appendix B3. It should be noted that these parameters are those that have been reviewed and approved by both the RVCA and City of Ottawa as part of the 2017 Existing Conditions Report.

6.1.4 Snowmelt

Snowmelt is an additional mechanism by which runoff may be generated in a continuous simulation model depending on the temperature. The current PCSWMM software platform utilizes the Canadian SWMM snowmelt routines with extensions for long term continuous modelling.

Snowfall rates are determined directly from hourly precipitation data by using a pre-set temperature: snowfall will occur when the temperature is below the pre-set point and rainfall will be triggered when above it. Snowmelt is handled differently by PCSWMM, depending on the occurrence of rainfall. During rain on snowmelt events, the model accounts the rainfall intensity and the air temperature as well as the saturation vapor pressure. When snowmelt occurs without any rainfall, the snowmelt is linearly proportional to the air temperature, which varies with the user supplied melt coefficients. The parameters used in the snowmelt module are detailed in Appendix B3. It should be noted that these parameters are those that have been reviewed/approved by both the RVCA and City of Ottawa as part of the 2017 Existing Condition reviewed and approved by both the RVCA and City of Ottawa as part of the 2017 Existing Conditions Report.

For the existing conditions model, it has been assumed that all snow occurs on pervious land cover given that it does not include any impervious surface which means that there is no snow removal.

6.1.5 Southwest Pond

The continuous simulation model extent includes the existing man-made pond in the south-west corner of the site. The pond forms a low point on the site which means that all flow contributing to the pond is infiltrated or evaporated until it reaches a spill elevation, estimated to be around 300mm above the natural water level. The pond has been included in the model using the LID components in the SWM Engine as this allows the infiltration from the pond to be included in the hydrology rather than a hydraulics component. Note that the seasonal infiltration pattern does not apply to LID components and therefore the infiltration is conservative for the existing condition as infiltration will occur in the pond in the model during the winter months.

Table 6-3: LID Parameter Summary

LID Parameter	Value	Notes
Berm Height (mm)	300 mm	Consistent with total ponding depth in pond
Vegetation Volume (fraction)	0	Ignored for the pond
Surface Roughness (Manning's n)	0	Not used for the pond

LID Parameter	Value	Notes
Surface Slope (%)	0	Not used for the pond
Storage Height (mm)	1	Necessary to incorporate a storage layer
Void Ratio	0.99	Maximum allowable but minimum impact on results
Seepage Rate (mm/hr)	42.265	Consistent with infiltration rates provided by Paterson and spatially weighted across the pond catchment.
Clogging Factor	0	No clogging assumed
Underdrain Drain Coefficient	0	No underdrain applied

6.2 Continuous Simulation Results

A long-term simulation was carried out for the median of each of the infiltration ranges of each block defined by Paterson in their Geotechnical/Hydrogeological Investigation. The continuous simulation results have been summarized for each of the three (3) subwatersheds as shown in Table 6-4, below. Note that the Rideau River does not receive any runoff from the S1 Area, but infiltrated rainfall does contribute to the groundwater catchment for the receiver. This is reflected in the results in the table.

Table 6-4: Water Budget Continuous Simulation Results

Annual Water Budget Component	Annual Average Depth to Jock River (mm)	Annual Average Depth to Mud Creek (mm)	Annual Average Depth to Rideau River (mm)	Area Weighted Total (mm)	Budget %
Precipitation	864	864	864	864	100%
Evapotranspiration	509	531	509	513	59%
Infiltration	296	314	286	297	34%
Surface Runoff	83	60	0	61	7%

Based on the above long-term simulation results, infiltration accounts for approximately 34% of the total annual precipitation of 864 mm, while surface runoff accounts for approximately 7% on a yearly average.

The 2017 BSUEA found that infiltration accounted for 40% of the water budget, however this did not include the seasonal infiltration pattern nor the existing pond. With these changes the value of 34% appears to be consistent with the previous results.

7.0 Existing Infrastructure and Servicing Summary

7.1 General

A detailed review of existing and planned infrastructure in the vicinity of the BSUEA was carried out as part of the Existing Conditions Report (JLR, 2017). A subsequent review was conducted as part of JLR's 2021 MSS Addendum which included more recent information associated with the former aggregate extraction parcels (Brazeau and Drummond properties).

As part of this Existing Conditions Report, the review of the most up to date information for recent developments was undertaking (refer to Section 3.0 for details).

In light of the above, Section 7.2 to 7.4 is an updated review of linear infrastructure in the vicinity of the S1 Area and BSUEA.

7.2 Trunk Wastewater Servicing

The existing and planned sanitary sewer systems located easterly and northerly from the proposed S1 Area were reviewed to identify potential connections points, if any, with available residual capacity, gravity connection, and opportunities and constraints for sewer extensions.

As previously noted, the sanitary design sheet, initially developed as part of the BSUEA MSS, and further revised as part of the design for the Quinn's Pointe Stages 2-4 and the 2019 Serviceability Study was used to assess residual capacity along the downstream sanitary sewer system.

This assessment was updated to reflect the latest design information supplied by the city for the development within the Brazeau, Drummond, ABIC lands, Meadows and Mattamy subdivisions. Additionally, the Master Design Sheet was revised to account for the latest peak wastewater flows from the S1 Lands (prepared by JLR) and S2 Lands (obtained from Arcadis), which located in the northeast quadrant of the Greenbank Road/Barnsdale Road intersection. The above information was reviewed to update the populations and was used to calculate sanitary peak flows and identify residual capacities along the downstream system. The Master Sanitary Design Sheet (refer to Appendix B4) and Master Sanitary Drainage Plan (Figure 7-1) was used to assess available residual capacities. The wastewater servicing trunk network along the northern and eastern perimeter of the S1 Area is as shown on Figure 7-2.

Servicing for the Brazeau and ABIC Lands consists of local 200 mm diameter sanitary sewers which eventually discharge into 300 mm and 375 mm diameter sanitary sewers on Haiku Steet and Dundonald Drive respectively. The 375 mm sanitary sewer on Dundonald Drive outlets into the 375 mm diameter trunk sanitary sewer along the Realigned Greenbank Road corridor, which in turn outlets into the Cambrian Road trunk sanitary sewers (500 mm and 750 mm in diameter). These sanitary sewers are currently existing as displayed on "geoOttawa" and have been depicted on Figure 7-2.

Servicing for the Drummond Lands consists of a local 200 mm diameter sanitary sewer system flowing northerly along Elevation Road where it merges into a shared sanitary sewer system within the Tamarack subdivision and eventually discharges into the Cambrian Road 500 mm diameter trunk sanitary sewer. The eastern portion of the Lands is serviced by a local sanitary

sewer that discharges into a 375 mm diameter trunk sanitary sewer along the Realigned Greenbank Road corridor, which flows northerly until discharging to the Cambrian Road 500 mm diameter sanitary sewer system. From this confluence, wastewater flows are conveyed easterly by the Cambrian Road 500 mm/600 mm/750 mm diameter trunk sanitary sewers until discharging into the Greenbank Road 900 mm diameter trunk sanitary sewer. These sanitary sewers are all existing as displayed on “geoOttawa” and have been depicted on Figure 7-2.

Based on the review of the residual capacity and elevation of the above-noted outlets, none of the sanitary sewers can provide a gravity connection with sufficient residual capacity to accommodate wastewater flows from the future S1 Area.

The latest wastewater servicing strategies developed for the Quinn’s Pointe Subdivision (Stages 2-5) were also reviewed. These strategies consisted of the following four (4) sanitary sewer outlets connecting to the existing Greenbank Road trunk sanitary sewers:

1. A connection to the most southern section of the Greenbank Road 600 mm diameter trunk sewer via the Barnsdale Road 375/450 mm trunk sanitary sewer.
2. A connection to the Greenbank Road 600 mm diameter trunk sanitary sewer via the Cappamore Drive 200/300 mm diameter trunk sanitary sewer.
3. A connection to the Greenbank Road 900 mm diameter trunk sanitary sewer via the River Mist trunk sanitary sewer (200 mm to 375 mm diameter) and Cambrian Road trunk 750 mm diameter sanitary sewer.
4. A connection to the Greenbank Road 600 mm diameter trunk sanitary sewer via the Kilbirnie Road 200 mm diameter sanitary sewer.

FIGURE 7-2

File Location: P:\26000\26610-300 - Barrhaven South C1-C2 Lands\05-Production\01-Civil\Figures\26610-300 C Figure 7.dwg

PLOT DATE: September 19, 2024 11:08:20 AM

Based on the above-noted servicing strategies, servicing outlets described under Item no. 2 to Item no. 4 do not have residual capacity to accommodate any of the S1 Area. Thus, wastewater flows from the S1 Area would need to be accommodated by the servicing connection to the Greenbank Road 600 mm diameter trunk sewer via the 375/400 mm trunk sanitary sewer on Barnsdale Road.

The above-noted sanitary sewers and connections are displayed on Figure 7-2.

7.2.1 Sanitary Sewer Outlet

The potential outlets noted in Section 7.1 revealed that the infrastructure within the existing Quinn's Pointe Subdivision (Servicing Strategy No. 1) could potentially serve as an outlet and accommodate the wastewater flows from the S1 Area. Thus, only the Barnsdale Road 375 mm diameter trunk sanitary sewer has residual capacity to accommodate part or all the S1 Area at Stub 2 (west of MHSAN77189 per geoOttawa).

7.2.1.1 Planned Trunk Sanitary Sewer

To provide an outlet connection from the S1 Area to an existing trunk sanitary sewer, a westerly extension of the Barnsdale Road 375 mm diameter sanitary sewer could provide the necessary capacity, from Stub 2 (west of MHSAN77189 per geoOttawa) to the southeast limit of the S1 Area. This extension, not shown on Figure 7-2, will be reviewed as part of the upcoming Master Servicing Study.

7.2.1.2 Available Capacities

The available capacity along the existing Barnsdale Road 375 mm diameter trunk sanitary sewer was reviewed to assess whether the system could service additional lands outside of the Quinn's Pointe Subdivision. To complete this task, the design sheets prepared to support the detailed design of the Quinn's Pointe Stages 2-4 and future Stage 5 were reviewed to identify the limiting pipe reach in terms of available residual capacity. This review showed that the limiting residual capacity along the Barnsdale Road trunk sanitary sewer was pipe reach MH 203 to MH 202 as shown in Table 7-1, below.

In parallel to the above, a similar task was completed to assess the limiting sewer reaches further downstream. To complete this review, the Master Sanitary Design Sheet prepared as part of the BSUEA MSS and further refined as noted in Section 7.2 (above), which was also revised to reflect the latest design flows for Stages 2-4 and both future S1 and S2 Lands. This review showed that the limiting residual capacity was along pipe reach MH200C to MH45 and pipe reach MH435A to MH501A along the trunk sanitary sewer along Greenbank Road. Details regarding this limiting pipe reach is also included in Table 7-1, below.

Table 7-1: Available Residual Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Limiting Pipe Reach	Residual Capacity (L/s)
Barnsdale Road	MH 203 to MH 202	117.1

Trunk Sanitary Sewer	Limiting Pipe Reach	Residual Capacity (L/s)
Greenbank Road	MH200C to MH45	8.7
Greenbank Road	MH435A to MH501A	95.6

As part of the upcoming MSS, peak sanitary loadings will be calculated for the approved Concept Plan to determine whether the above-noted limiting sewer reaches can accommodate the S1 Area.

7.3 Water Servicing

7.3.1 Existing Federmains

Currently, potable water is supplied to the southerly portion of the existing Barrhaven South Community by several feedermains located to the north and east of the S1 as depicted on Figure 7-3. A brief description of these feedermains follows.

- Greenbank Road 406 mm Diameter Feedermain
  This feedermain extends southerly from the Jock River to the southerly limit of the current Urban Boundary at Barnsdale Road.

- Cambrian Road 406 mm Diameter Feedermain
  This feedermain extends westerly from Greenbank Road to Elevation Road where it is currently capped.

- River Mist Road 305/203 mm Diameter Feedermain
  This feedermain extends the entire length of River Mist Road from River Run Avenue up to the Russett Terrace as a 305 mm diameter and then southerly to Cappamore Drive as a 203 mm diameter watermain.

- Elevation Road 305 mm diameter Feedermain
  This feedermain extends southerly, from Cambrian Road to the southerly limit of the current Urban Boundary within the Ridge Subdivision.

- Obsidian Street 305 mm diameter Feedermain
  This feedermain extends southerly, from Dundonald Drive to the southerly limit of the current Urban Boundary within the Ridge Subdivision.

- Cappamore Drive 305 mm diameter Feedermain
  This feedermain extends westerly within the Quinn's Pointe Subdivision, from Greenbank Road to westerly limit of the current Urban Boundary.

- Barnsdale Road 203 mm diameter feedermain
  Although this 203 mm diameter watermain is a local watermain, it could also act as a feedermain to the southern portion of the S1 Area. Currently, it spans from Greenbank Road westerly to a point east of Inver Lane.

7.3.2 Future Feedermains

As part of the long-term infrastructure needs, future feedermains have been planned but some have not yet been constructed within the current Urban Boundary. These future planned watermains, which have been identified as dashed lines on Figure 7-3.

- Realigned Greenbank Road 305 mm diameter feedermain
  This feedermain is planned to be extended northerly by others, from Kilbirnie Drive to Cambrian Road.

- Cambrian Road 406 mm diameter feedermain
  This feedermain, which is identified in the 2024 Infrastructure Master Plan, is planned to be extended westerly by others, from Elevation Road to Borrisokane Road and then span southerly to connect with the future logistics and commercial lands fronting Borrisokane Road.

Based on the recently issued IMP (June 2024), other watermains have been planned in the South Barrhaven Community that will improve the supply characteristics to the S1 and S2 Lands and increase resiliency. Two (2) watermain projects have been scheduled for implementation between 2029-2034, as follows:

- The Greenbank 610 mm diameter trunk watermain
- The 406 mm diameter trunk watermain along Cambrian Road/Borrisokane Road.

7.3.3 Water Supply and Current Operating Pressures

The Barrhaven South Community is currently being serviced from Pressure Zone BARR which receives its supply from Pressure Zone 2W via the two (2) source transmission mains: The Woodroffe Avenue 1200 mm diameter watermain, from Baseline Road to Fallowfield Road; and the Fallowfield Road 762 mm diameter watermain.

The Barrhaven Reservoir, located adjacent to Fallowfield Road, acts as balancing storage for Zone 2W and feeds the Barrhaven Pumping Station (BPS), which boosts water to the Pressure Zone BARR.

Based on a recent boundary condition request, the current hydraulic grade line (HGL) elevations and corresponding operating pressures under peak hour demand at the connection points with the S1 Area are expected to be around 140 m which would yield pressures between 43 psi to 50 psi. Similarly, under a fire flow condition, the HGL and corresponding pressures would fluctuate between 26 psi to 36 psi depending on the location and the extent of the fire flow requirements.

7.3.4 Zone Reconfiguration and Operating Pressures

Findings presented in the City of Ottawa Water Supply Optimization Study Report (Delcan, 2008) and the Draft 2014 BSMSSA showed that a reconfiguration of pressure zones within the South Urban Community, which includes the S1 and S2 Lands, would eliminate the need for a new booster pumping station, minimize system fragmentation (dead-ends), and generally improve system reliability and operation.

FIGURE 7-3

File Location: P:\26000\26610-300 - Barrhaven South C1-C2 Lands\05-Production\01-Civil\Figures\26610-300 C Figure 7.dwg

PLOT DATE: September 19, 2024 11:08:23 AM

This recommended zone reconfiguration would consist of an expanded Zone 3C, now being referred as Pressure Zone SUC. Pressure Zone SUC would include the South Barrhaven Community (including the future S1 and S2 Lands) and Gloucester South Community as well as the Airport Lands.

In addition to the implementation of several significant water projects over the next five (5) years, the two (2) watermain projects listed in Section 7.3.2 are scheduled for implementation in 2029-2034 as noted in the 2024 IMP. As such, the Riverside South Elevated Tank and Ottawa South Storage upgrade are scheduled for implementation between 2025-2029.

Based on the city's current project implementation schedule, the pressure zone reconfiguration to the common Pressure Zone SUC is scheduled to be in effect in 2027. Once the reconfiguration is completed, the supply characteristics of the reconfigured Pressure Zone SUC will enable to meet future growth, and reliability needs within both South Barrahven Community (including S1 and S2 Lands) and South Urban Community.

Based on a recent boundary condition request, the HGL elevations and corresponding operating pressures following the SUC pressure reconfiguration are expected to slightly increase above the current condition to around 141 m which would yield pressures between 45 psi to 53 psi under peak hour demands. Similarly, the corresponding operating pressures during a fire flow condition are expected to slightly decrease between 23 psi to 33 psi depending on the location and the extent of the fire flow requirements.

7.4 Stormwater Servicing and Stormwater Management

7.4.1 Barrhaven South Stormwater Management Servicing

The Barrhaven South Community is serviced by five (5) main stormwater management facilities which were identified as part of the Jock River Reach One Subwatershed Study (2007). These facilities were to provide quality control and meet an enhanced protection level. These five (5) facilities, located south of the Jock River, are referred to as the Corrigan, Todd, Clarke, Borrisokane and Greenbank facilities. A summary for each of these five (5) facilities can be found in JLR's 2017 Existing Conditions Report.

The review carried out as part of the 2017 Existing Conditions Report had shown that none of the five (5) facilities noted above were designed with any quality control volume dedicated to the urbanized BSUEA nor S1 Area.

The MSS review identified that the Corrigan Pond was intended to serve as the dedicated outlet for a small portion of the BSUEA (Quinn's Pointe Subdivision) under the pre-development drainage condition. Consequently, the two (2) existing dry ponds within the existing Quinn's Pointe Subdivision were designed to capture and limit the peak flows to the prescribed flow allowance to the Greenbank Road trunk storm sewer system, set at the pre-development contribution.

Given that major overland flow from the Quinn's Pointe Subdivision (Stages 4 and 5) could not sheet flow towards Greenbank Road, the servicing solution recommended that the dry ponds be sized to limit the post-development flows to pre-development levels and to contain on-site the major overland flow.

Since the Corrigan Pond did not have sufficient capacity for water quality control of the runoff from the BSUEA, servicing of the Quinn's Pointe developments had to integrate water quality features in addition to the water quantity controls prior to discharge to the Greenbank Road trunk storm sewer.

Servicing within the BSUEA incorporated a third pipe infiltration system, also known as an Etobicoke Exfiltration System (EES) to enhance groundwater recharge and to provide water quality treatment. The EES was restricted to local roads to limit chlorides from road salt entering the groundwater system. An Oil Grit Separator (OGS) unit was included on the downstream end of the collector storm sewer network to augment the water quality control for the collector roads within the BSUEA.

Due to topography of the BSUEA, a major system spill-over dry pond was implemented as part of the servicing, located outside of the BSUEA in the southeast corner of the now S1 Area. The pond collects major system overland flow from the western part of the BSUEA (between future realigned Greenbank Road and western OP limit) and discharges it at a controlled rate of 330 L/s into the storm sewer system on Inver Lane.

7.4.2 EES Monitoring

Monitoring of the EES was made a condition of approval by the city to gather data and confirm the suitability of the design parameters adopted during the preliminary design of the EES as part of the 2017 BSUEA. To facilitate monitoring, the city advised that it should be completed using the SmartLevel™ technology supported by Link Utility Technology as it has been tested and adopted by the City's Operation Group. In parallel, monitoring of rainfall events was carried out using the SmartRain™ system to collect real-time precipitation data. The objective of the monitoring was as follows:

- Determine the spill occurrences and identify under which rainfall events results in spills into the conventional storm sewer system occur; and
- Determine the drawdown time and identify the time it takes for the drawdown of the EES following a rainfall event.

Three (3) monitoring locations have been set up within Quinn's Pointe Stages 2 and 3. The locations were established to cover various sizes of serviced areas; a small area at MHST82176 (2.6 ha), a mid-size area at MHST82182 (7.6 ha) and a larger serviced area at MHST83698 (20.5 ha).

Level monitoring was initiated once a minimum occupancy of 80% of the serviced area was achieved. Level monitoring was initiated in June 2022 for one of the stations while monitoring for the other two (2) stations was initiated in November 2022. Given that the EES was sized to capture a 22 mm precipitation event, the review of the monitored data mainly focused on events of 22 mm or greater magnitude. During the period spanning from July 1, 2022, to February 29, 2024, a total of 108 rainfall events were recorded, from which a total of fourteen (14) events exceeded 22 mm when the minimum daily temperature was above 0^{o}C.

The fourteen (14) recorded precipitation events spanned between ≈25 mm to 92 mm with most of the events between 25-40mm. The most significant event of 92 mm occurred over 46 hours

and its 12-hour intensity was established to be comparable to a 1:10-year event when compared to the Ottawa IDF statistics.

Based on the review of the recorded data, the following was observed:

A single spill was observed at MHST82716 (Robin Easey Avenue and Teelin Circle intersection) which was triggered after the first 22.5 mm of the 92 mm precipitation event. Hence, this spill is consistent with the design basis of the system.

Three (3) spill events were recorded at MHST83698 (Edenderry Way and Oranmore Lane intersection) which was triggered after 22 mm (i.e., 37 mm and 39 mm) of events greater than 54 mm except of one event that a spill was observed after 12 mm of the 58 mm event. Based on the review of the data, this rainfall event occurred during a period of high groundwater levels with slower drawdown periods and higher base depths. In addition, this precipitation event of August 10, 2023 (58 mm), started 48 hours after the end of the August 7, 2023, event which was 54 mm in total, while drawdown of that event was still occurring.

The drawdown rates were also assessed based on the review of the level recordings. This review showed that the overall average drawdown rate is much higher than the design rates used in the modelling undertaken as part of the BSUEA MSS given that a safety factor of 2.5 was applied to the hydraulic conductivities measured by Paterson. The increased drawdown rate should allow for a greater capture of back-to-back events provided that groundwater levels do not impede the actual drawdown time.

Based on the guidance from the Hydrogeological Report for the S1 lands, high groundwater levels in the southern portion of the site have the potential to restrict and limit the effectiveness of a sub-surface infiltration system given that it will be submerged. The most southern monitoring location, MHST83698, recorded elevated baseline levels in the spring of 2023 to the late summer 2023 and in the summer of 2024. The nature of these elevated levels indicates that groundwater is entering the manhole via the EES and, although the monitoring report to date indicates that the 22mm event storms are still being infiltrated it may impact the operation and maintenance over the lifespan of the system.

7.4.3 Storm Servicing Connection Points

There are four (4) storm sewer connections located on the boundary of the S1 Area, which are shown on Figure 7-4. The connections are:

- Northern Connection – Elevation Road
  There is a potential connection on the northern boundary of S1 Area at Elevation Road. At that location (≈10 m off the S1 Area limit), there is a 300 mm diameter storm sewer system flowing in a northerly direction to the Haiku Street 1650 mm diameter storm sewer system which eventually merges with the 2250 mm diameter storm sewer along Expansion Road. Upon further review of the design documents, there was no flow allowance made for the S1 Area in the Elevation Road 300 mm diameter storm sewer.

PLOT DATE: September 19, 2024 11:08:27 AM

- Northeastern Connection - Planned Kilbirnie Drive/Realigned Greenbank Road
  There is a potential connection on the northeastern boundary of the S1 Area along Kilbirnie Road. The planned Kilbirnie Road storm sewer will flow easterly to the planned Realigned Greenbank Road trunk sewer system, which is currently under design by Stantec.

- Southeastern - Dry Pond
  There is a potential connection on the southeastern boundary of the S1 Area to the existing spill-over dry pond that is currently located within the S1 Area. This facility is serviced by a single outlet sewer, being a 900 mm diameter storm sewer, located east of the dry pond within a servicing easement. The 900 mm diameter storm sewer outlets into the 1500 mm diameter storm sewer along Inver Lane.

- Other Storm Connection
  In addition to the above-noted storm sewer outlets, there is a watercourse connection located at the southwestern boundary of the S1 Area which currently serves as the natural outlet for the properties. The connection point is to the Thomas Baxter Municipal Drain.

8.0 Opportunities and Constraints

8.1 Drainage Network

The review of LiDAR data and findings of the Environmental Inventories completed by Arcadis showed that there are no waterways or watercourses within the limits of the S1 Area. The lack of waterways is generally indicative of the low frequency in the flow generation potential for a given area. This has been corroborated by the measured saturated hydraulic conductivities carried out by Paterson.

As part of the upcoming storm servicing, some constraints such as modification to drainage may be reviewed and/or permitted as part of the MSS. These modifications will need to follow the appropriate levels of approvals. Any modification to the hydrological regime of the Thomas Baxter Municipal Drain will need to be completed in accordance with the Ontario Drainage Act.

The Thomas Baxter Municipal Drain is immediately south of the Study Area at Barnsdale Road and carries flow from the S1 Area and Barnsdale Road to Mud Creek. Based on topography, approximately 68 ha of the S1 Area (refer to drainage limits depicted on Figure 5-1) is tributary to Mud Creek via the Thomas Baxter Municipal Drain.

8.2 Aquatic Habitat and Natural Heritage

A Natural Heritage Existing Conditions Report was initially issued by Arcadis in October 2024. A revised Natural Heritage Existing Conditions Report was subsequently issued in February 2025 to address comments.

Field surveys completed by Arcadis showed that the headwater drainage feature in the southern extents of the S1 Lands has ephemeral flow, limited riparian function, contributing function to fish habitat, and limited function for terrestrial habitat. As such, the management recommendation is “mitigation”, and this feature will be realigned and maintain the conveyance of flows and the

contributing functions of the feature. Coordination during the upcoming MSS will be carried out with Arcadis' biologist.

The completion of the field surveys indicated that the S1 Lands does contain significant wildlife habitat (Candidate Bat Maternity Colony and Confirmed Woodland Raptor Nesting). Birds showing breeding indicators within the S1 Lands were limited to common species for the area.

The field surveys did not find any breeding habitat for Species at Risk, although two Species of Conservation Concern (monarch and eastern wood-pewee) were observed.
There are no wetlands present within the S1 Lands; however, it does contain two woodlands identified as "Significant" (Woodland A and Woodland B).

The development of the S1 Lands will lead to the loss of general flora and fauna habitat, and some mature trees within Woodland B. This loss can be compensated for through plantings of native trees and shrubs as included in future landscape plans.

Due to the disturbed nature of the S1 Lands, and low ecological value, from an environmental perspective the S1 Lands are an excellent candidate for the proposed development.

8.3 Floodplains

The S1 Lands are not restricted by any regulation floodplains within or adjacent to its boundary.

8.4 Water Quantity Control

Water quantity criteria will be affected by site constraints and municipal and provincial requirements. Water quantity control for lands that drain to the Jock River will be governed by available capacity in existing minor and major systems in the existing Quinn's Pointe Subdivision. Since the existing and planned infrastructure in Quinn's Pointe was designed to service lands up to the current Urban Boundary, there is limited capacity in existing minor and major systems in the Quinn's pointe Subdivision.

For lands that drain to Mud Creek, flows will need to be limited to the capacity of the Thomas Baxter Drain. Any additional flow discharge to the Thomas Baxter Drain should not aggravate the risk of flooding. Any modifications to this Drain or to its flow regime will need to be assessed and approved in accordance with the Drainage Act, Chapter D.17, R.S.O., 1990.

A meeting was held on August 9, 2024, to discuss the potential impact of the future urbanization of the S1 Area regarding the Ontario Drainage Act. The meeting was attended by both City's Drainage Superintendents, staff from city and Minto as well as JLR. During this meeting, JLR noted to the Drainage Superintendents that a further disconnection of the majority of the S1 Area would likely be confirmed as part of the upcoming MSS. Based on preliminary grades developed by JLR within the S1 Area , it would appear that a small post-development drainage area (≈2 ha) would remain connected to the Thomas Baxter Municipal Drain while the majority of the S1 Area (> 60 ha) would be disconnected from the Municipal Drain.

A subsequent E-Mail, prepared by the Drainage Superintendent, confirmed that the disconnection would follow a Section 65(4) of the Drainage Act and given the size of the area remaining within the serviced area of the Thomas Baxter Municipal Drain it would not warrant a request under

Section 65(1) nor a Section 78, pending the interpretation of a licensed Drainage Engineer which will be appointed by council.

8.5 Water Quality Control

Water quality treatment will need to be provided in accordance with the relevant subwatershed studies. The Jock River Reach One Subwatershed Study states that, for areas tributary to the Jock River, an enhanced level of water quality treatment protection, in accordance with the MOE 2003 SWMPDM, is required. Similarly, an enhanced level is to be targeted for the Thomas Baxter Municipal Drain / Mud Creek. Water quality will also need to account for the Consolidated Linear Infrastructure Environmental Compliance Approval (CLI-ECA), which was issued in December 2024.

8.6 Infiltration

The Hydrogeological Study undertaken by Paterson confirms that, in general, soils within the S1 Area have a moderate to high hydraulic conductivity (refer to Figures included in Paterson's Appendix 2).

Based on Paterson's In-Situ Infiltration Testing completed using the Pask Permeameter (refer to Section 4.3.6 of their Report), field saturated hydraulic conductivity (K_{fs}) values of the unsaturated overburden material ranged from 1.1×10^{-7} m/s to 8.5×10^{-5} m/s with estimated unfactored infiltration rates of 30 mm/hr to 152 mm/hr. However, the Report notes that the majority of the infiltration test completed estimated infiltration rates between approximately 50 mm/hr to 100 mm/hr which is similar to the testing completed for the BSUEA.

Paterson's latest infiltration testing is included in their Appendix 3, and findings summarized on their Figure entitled "Preliminary Soil Infiltration Rates – Drawing PG6197-4 (refer to Paterson's Appendix 2 for Drawing). This data shows shallow groundwater encountered in the southern portion of the S1 Area. The moderate hydraulic conductivity soil is observed in the southern portion while the highest hydraulic conductivity soils are observed in the northwestern portion of the study area. Soils having the highest hydraulic conductivity are considered to act as a recharge zone for underlying aquifers and generally suitable for providing groundwater recharge and appropriate practices must be implemented to maximize the rate of infiltration. However, the shallow groundwater in the southern portion of the Study Area will prevent the use of infiltration practices.

Non-structural Best Management Practices such as discharging impervious runoff, including roof runoff, to lawns are required regardless of soil capacity, in accordance with the Jock River Reach One Subwatershed Study. In addition, the study should consider the potential to incorporate Low Impact Development (LID) measures in areas that are conducive to infiltration, to reduce the anticipated infiltration deficit and maintain pre-development infiltration levels to the esker.

Based on fulfilling the objective of maintaining pre-development infiltration levels, storm servicing solutions incorporating infiltration measures will be reviewed and developed, when feasible, at the MSS level to achieve water balance. These infiltration measures will be incorporated within all areas of the S1 Area where groundwater levels will allow the construction of this measure, striving to maintain pre-development infiltration levels in the areas with low groundwater elevations.

As part of storm servicing, some constraints such as modification to drainage may be reviewed and/or permitted as part of the MSS. However, these modifications will need to follow the appropriate levels of approvals.

The Mud Creek Subwatershed Study identified that there are significant groundwater recharge areas including the Kars Esker, a Mississippi-Rideau Source Water Protection Region Significant Groundwater Recharge Area, across the majority of the western portion of the S1 Area. These pre-development recharge conditions must be maintained. A water balance will be required to demonstrate adherence to this requirement. The Mud Creek Subwatershed Study also recommends avoiding infiltration of poor-quality runoff from paved surfaces without pre-treatment, and to consider the use of LID and Best Management Practices for stormwater management quality and quantity control.

8.7 Existing Servicing Infrastructure

The following opportunities and constraints have been identified for the existing and planned servicing infrastructure in Barrhaven South. These will be reviewed and evaluated in greater detail as part of the MSS

8.7.1 Wastewater Servicing

Wastewater servicing for the S1 is ultimately governed by the available residual capacities in the existing downstream trunk sanitary sewers in the Quinn's Pointe Subdivision as none of the sewers within the Ridge Subdivision included capacity for the lands. The previous Sanitary Master Design Sheet developed as part of the 2019 Serviceability Study was revised based on information supplied by the city as described in Section 3.0. This Design Sheet is included in Appendix B4.

Based on a gross area of 65 ha and a population density of 63 persons/ha, the equivalent residential development population for S1 Area would be approximately 4095 persons. Using this population and an average flow rate of 280 L/cap/day, the theoretical residual capacity for the limiting pipe reaches in Table 8-1 was evaluated. The peaking factors for each limiting pipe reach is based on the cumulative population which includes the contribution from the S1 Area. The projected peak flow based on the above assumptions were subtracted from the residual capacity of the pipe reaches which has been summarized in Table 8-1 below.

Table 8-1: Available Tributary Area Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Limiting Pipe Reach	Net Anticipated Residual Capacity (L/s)
Barnsdale Road	MH203 to MH202	117.1
Greenbank Road	MH200C to MH45	8.7
Greenbank Road	MH435A to MH501A	95.6

As indicated in Section 7.2 of this Report, the existing Barnsdale Road trunk sanitary sewer could serve as the main outlet for S1 Area.

Based on the theoretical peak flow calculations summarized in Table 8-1 above, the existing Greenbank Road trunk sanitary sewer has sufficient capacity to accommodate the peak flows generated within the S1 Area.

Based on the wastewater modelling supporting the 2024 IMP, no constraints with the existing Greenbank Road trunk sanitary sewer (downstream of at MH 522A – south of Jock River), was identified. This is based on actual real time monitoring data carried out by the city of Ottawa.

8.7.2 Water Servicing

Low pressures (i.e., less than 40 psi) could be encountered during peak hour demand conditions in the S1 Area, in localized areas, where the existing ground elevation is relatively high such as the knoll in the northern area that spans into the Ridge Subdivision at Appalachian Circle. Further opportunities and constraints will be identified upon completion of a detailed Hydraulic Network Analysis (HNA) as part of the S1 Area MSS.

8.7.3 Stormwater Servicing and Stormwater Management

As noted in Section 7.4, residual capacity only exists in the 900 mm diameter trunk storm sewer in the Quinn's Pointe Subdivision which services the spill-over dry pond, already located within the S1 Area. The residual capacity was estimated at 330 L/s as noted in Section 7.4.

9.0 Summary and Recommendations

The following provides a series of recommendations to be considered when preparing the S1 Area MSS, in the context of the opportunities and constraints discussed above.

9.1 Wastewater Servicing

Overall servicing for the S1 Area will convey wastewater flows towards the Barnsdale Road sanitary sewer extension as the elevation of the system can provide a gravity connection. The captured flow will then be conveyed to the existing Greenbank Road trunk sanitary sewer flowing northerly.

To minimize infiltration into the proposed local sanitary sewers in the southern portion of the S1 Area where it is anticipated to be below the groundwater table, the latest MECP guidance entitled "Design Criteria Final, May 31, 2023" should be followed.

Sections 2.9 and 2.10 of the above publication provides requirements for sanitary sewers and maintenance holes installed below the high seasonal groundwater table to include a series of measures where pipe joints and connections are to be designed to: to withstand pressures of 1.25 times the pressure exerted, be externally wrapped by waterproofing membranes, etc.

9.2 Water Servicing

Water servicing for the S1 Area will be developed to fulfill regulatory requirements under both domestic and fire flow conditions. It is anticipated that there will be an area that may not fulfill the minimum pressure requirements during domestic demand conditions, due to topography. As a result, this localized area may require oversized service laterals to minimize headlosses. This condition, as well as water servicing specifics such as watermain looping and sizing of the feedermains for the S1 Area, will be addressed at the MSS stage by a hydraulic network analysis (HNA). The HNA will be carried out in accordance with the most recent Design Guidelines and Technical Bulletins.

9.3 Stormwater Servicing and Stormwater Management

Section 7.4 identified the 900 mm diameter trunk storm sewer in Quinn's Pointe Subdivision as the gravity outlet for the S1 Area. Given its limited capacity (estimated at 330 L/s), a proposed end-of-pipe facility will be required at the current location of the spill-over pond. This future facility will be sized to accommodate minor and major system flows from the S1 Area as well as the major overland flow for an area in the existing Quinn's Pointe Subdivision west of Realigned Greenbank Road. This facility will need to be sized to maintain the integrity of the existing Quinn's Pointe storm sewer system as well as the Greenbank Road storm sewer system. Major system flows would also be conveyed overland to this future pond.

LID measures to promote infiltration are to be incorporated as part of the overall servicing of the S1 Area to achieve the targeted water balance to preserve the Kars Esker. In areas where LIDs cannot be implemented due to high groundwater table, other quality control measures will be reviewed.

This report has been prepared by J.L. Richards & Associates Limited for Minto Communities Canada's exclusive use. Its discussions and conclusions are summary in nature and cannot properly be used, interpreted or extended to other purposes without a detailed understanding and discussions with the client as to its mandated purpose, scope and limitations. This report is based on information, drawings, data, or reports provided by the named client, its agents, and certain other suppliers or third parties, as applicable, and relies upon the accuracy and completeness of such information. Any inaccuracy or omissions in information provided, or changes to applications, designs, or materials may have a significant impact on the accuracy, reliability, findings, or conclusions of this report.

This report was prepared for the sole benefit and use of the named client and may not be used or relied on by any other party without the express written consent of J.L. Richards & Associates Limited, and anyone intending to rely upon this report is advised to contact J.L. Richards & Associates Limited in order to obtain permission and to ensure that the report is suitable for their purpose.

MEMO

Date: May 31, 2024

To: Robin van de Lande, City of Ottawa

From: Guy Forget P.Eng.

CC: John Bougadis M.A.Sc., P.Eng. (City of Ottawa), Curtiss Scarlett P.Eng. (Minto Communities – Canada)

Subject: S1 Urban Expansion Area– Terms of Reference

JLR No.: 26610-300

The S1 Urban Expansion Area (S1 UEA) will encompass ≈68 ha of proposed development located west of the established Quinn's Pointe Subdivision, south of the established Ridge Subdivision, north of Barnsdale Road and east of Borrisokane Road, within the Barrhaven South Area. Based on the latest Concept Plan (version 37), the eastern portion of the S1 UEA will consist of proposed residential development (formerly referred as the C1 Lands) owned by Minto Communities while the western portion will consist of proposed commercial development (formerly referred to the C2 Lands) owned Minto Greenfield (Barrhaven South). Minto Communities Inc. – Canada is overseeing the progress of the Approval process on behalf of both Minto Communities and Minto Greenfield (Barrhaven South).

The approval of the S1 UEA will follow the Concept Plan Approval (CPA) process given that the parcel is relatively small, and that ownership is virtually by one single Owner being Minto. Several deliverables will be prepared on behalf of Minto in support of the CPA process.

Master Servicing Process

The MSS for the S1 UEA will be completed in accordance with Appendix C of the Infrastructure Master Plan "Guideline for Preparing Terms of Reference for Master Servicing Study (June 2023)", which sets out the deliverables required.

Task 1: Terms of Reference

This Term of Reference (TOR) for the S1 UEA was prepared in response to the City request that a Master Servicing Study (MSS) Terms of Reference (TOR) be prepared for the S1 UEA in accordance with the "Appendix C: Guideline for Preparing Terms of Reference for a Master Servicing Study, June 2023" included in the Draft Infrastructure Master Plan.

Task 2: Existing Conditions Report (ECR)

The ECR will consist of the following:

- Review and Consolidation of background reports and information.
- Inventory of Water Crossings and Watershed Delineation
- Hydrological Modelling and Capacity Analysis of Conveyance Systems
- Water Budget Modelling
- Floodplain Mapping and Geomorphological Assessment
- Review Existing Conditions: Wastewater, Water and Storm Servicing
- Identify Constraints/Opportunities and Recharge/Discharge Areas
- Evaluation and Assessment of Storm Design Criteria and Objectives

- Assist Drainage Engineer with Hydrological Calculations for the Thomas Baxter Municipal Drain
- Prepare Existing Conditions Report

Several background reports will be reviewed including:

- Barrhaven South Urban Expansion Area MSS (JLR, 2018)
- MSS Addendum for the Barrhaven South Urban Expansion Area (January 5, 2021)
- Technical Memo – The Ridge & Drummond lands (DSEL, April 7, 2020)
- SWM Report, The Ridge (Brazeau lands), (JFSA, June 2020)
- Design Brief – The Ridge (Brazeau lands) (DSEL July 27th, 2020)
- Design Drawings – The Ridge (Brazeau Lands) (DSEL, 2020-09-25)
- Design Brief – The Ridge SWM Pond (DSEL/JFA, June 2020)
- Site Servicing Plan – 3713 Borrisokane Road (ABIC) (DSEL, December 2019)
- Technical Memo – 3713 Borrisokane (ABIC) (Dillon, November 4, 2020)

In addition to the above, this task will include the review of other information provided by Minto, the City of Ottawa and/or the Rideau Valley Conservation Authority (RVCA), including:

- Land Ownership with boundary information.
- Recent air photography.
- Topographical maps.
- LiDAR as provided by the City of Ottawa.
- Surficial geology from the province.
- Land use and vegetation.
- Topographical surveys (from Minto).
- Floodplain mapping at the boundary of the S1 UEA, if applicable.
- Other information compiled by the Team's Geotechnical/Hydrogeological Engineer, Biologist and Transportation Engineer.

Task 3: Future Development Condition

The approved ECR will identify constraints and opportunities which will encompass physical, environmental, as well as servicing constraints that will be determined from the inventory of existing linear infrastructure and potential outlets. At such time, a further review of topographical maps and surveys will be completed as well as the drainage patterns identified under existing conditions.

Given that this project will follow the Concept Plan Approval (CPA) process and that the latest Minto Concept Plan (version 37) has been reviewed and revised based on the city and Fotenn's input, a single Concept Plan will be analyzed once it has been updated/revised to reflect the ECR's findings.

Task 4: Servicing Design Constraints and Develop Design Criteria

Servicing constraints will be identified for the existing systems at or near the boundary of the S1 UEA.

- Review Servicing Constraints defined in BSUEA MSS and other Reports
- Coordinate and Liaise with Geotechnical Engineer and Hydrogeological Engineer
- Coordinate and Liaise with Biologist

Task 5: Servicing Alternatives for Wastewater, Water and Stormwater Management, Including Preparation of Master Grading

JLR will develop potential servicing alternatives, when applicable, for wastewater, water, storm and stormwater management recognizing constraints identified through the Existing Conditions Report and Concept Plan.

Task 6: Evaluation of Servicing Alternatives, when applicable, and Identification of Recommended Wastewater, Water and Stormwater Management Solution

High-level servicing alternatives developed as part of Task 5, will be evaluated to confirm their adequacy and to identify the recommended servicing alternative for wastewater, water and storm/stormwater.

Task 7: Review/Develop Implementation and Phasing Plans and Prepare Cost Estimate

Task 8: Approvals

Approvals by various groups at the city of Ottawa will be sought as part of this MSS as well as other stakeholders. Based on the previous BSUEA MSS, coordination with Minto's subconsultants was carried out throughout the ECR and MSS. As part of the BSUEA MSS, the following groups were consulted:

- CPT Members (as needed)
- City of Ottawa Economic Development Services
- City of Ottawa Transportation Planning
- City of Ottawa Parks Forestry & Stormwater Services
- City of Ottawa Transit Customer Services and Planning
- City of Ottawa Parks and Facilities Planning Services
- City of Ottawa Infrastructure Services
- City of Ottawa Planning Services
- City of Ottawa Right of Way Heritage & Urban Design Services
- Ottawa Public Health
- Rideau Valley Conservation
- Ministry of the Environment, Conservation and Parks
- Ottawa Carleton District School Board (OCDSB)
- Conseil des écoles publiques de l'Est de l'Ontario (CEPEO)

EXISTING CONDITION REPORT – APPENDIX B
SWMHYMO MODEL DESCRIPTION

MINTO COMMUNITIES INC. & MATTAMY HOMES LTD.
BARRHAVEN SOUTH URBAN EXPANSION AREA

1.0 NASHYD

In catchment areas with an area of impervious less than 20% the NASHYD command was used.

<table>
<tr><th>Parameter</th><th>Units</th><th>Description</th></tr>
<tr><td>Catchment Area</td><td>ha</td><td>The catchment area was delineated using the supplied contours and took account of quarries. In the Pre-development model no changes are made to the catchment areas but the pits are assumed to be filled to the surrounding ground level.</td></tr>
<tr><td>CN</td><td></td><td>The modified CN* value is used in the model. The CN values are based on hydrological soil types from OMAFRA mapping and MTO Design Chart 1.08 and land cover as per the aerial photography. The MTO drainage manual Design Chart 1.09 was used to assign CN values. The following CN values have been used:
<table>
<tr><th rowspan="2">Land Cover</th><th colspan="4">CN for Hydrologic Soil Group</th></tr>
<tr><th>A</th><th>AB</th><th>B</th><th>BC</th></tr>
<tr><td>Asphalt</td><td colspan="4">98</td></tr>
<tr><td>Agricultural</td><td>39</td><td></td><td>61</td><td>68</td></tr>
<tr><td>Grass</td><td>39</td><td></td><td>61</td><td></td></tr>
<tr><td>Gravel</td><td>76</td><td>81</td><td></td><td></td></tr>
<tr><td>Pasture</td><td>39</td><td>50</td><td></td><td>68</td></tr>
<tr><td>Pond/Lake</td><td colspan="4">50</td></tr>
<tr><td>Unimproved Lands</td><td>49</td><td></td><td></td><td></td></tr>
<tr><td>Woodlot</td><td>30</td><td></td><td>58</td><td></td></tr>
</table>
The CN values were area weighted for each catchment area.</td></tr>
<tr><td>Initial Abstraction</td><td>mm</td><td>Initial Abstraction values are 0.075S for areas with CN value less than 70 and 0.1S for areas with CN values greater than 70. (Visual Otthymo Manual)</td></tr>
<tr><td>Time to Peak</td><td>hrs</td><td>The time to peak is 0.6 of the Time of Concentration which was calculated using Uplands Method.</td></tr>
</table>

2.0 STANDHYD

In catchment areas with impervious greater than 20% of the area, the STANDHYD command was used.

Parameter	Units	Description
Catchment Area	ha	The catchment area was delineated using the supplied contours and took account of quarries. In the Pre-development model no changes are made to the catchment areas but the pits are assumed to be filled to the surrounding ground level.
Imperviousness		The total imperviousness (TIMP) was calculated from land cover based on the aerial photography. Lands that are sealed such as parking lots or roads are included as impervious. The directly connected imperviousness (XIMP) (the percentage of impervious surface not routed through a pervious surface) is negligible as there is no storm sewer network to collect the flow from these areas.
Horton Coefficients		Horton methods are used to calculate the infiltration. The Horton coefficients entered are from the City of Ottawa manual and are typical for the Ottawa area. The values are f_c = 13.2 mm/hr, f_o = 76.2 mm/hr, k = 0.0015 s^{-1}.
Initial Abstraction	mm	Initial abstraction values are as per the City of Ottawa drainage manual: 4.67 mm for pervious areas and 1.57 mm for impervious areas.
Slope	%	Slope was read from the contour data and averaged across the catchment area for the pervious slope parameter. The impervious slope parameter is based on the cross grade on a typical road section.
Flow Length	m	The pervious flow length is based on the longest flow path from contour data, the impervious flow length is half a typical road width.
Manning's n		The pervious Manning's n value is 0.25 to be representative of sheet flow through grassland or pasture. Impervious Manning's n value is 0.013 to be representative of an asphalt surfacing.

Water Budget Analysis

EXISTING CONDITION REPORT – APPENDIX B3
PCSWMM WATER BUDGET MODEL DESCRIPTION

MINTO COMMUNITIES INC.
BARRHAVEN SOUTH PHASE 3 – S1 AREA

The tables below describe the parameters and values used for the water balance modeling in PCSWMM. In some cases values are required to be entered which, in this specific model scenario, are not used but must still be entered. Where a value does not affect the model or is not used the row is in grey.

1.0 CATCHMENTS

Parameter	Units	Description
Name	-	The name of the subcatchment. Format used is generally *EventModelID_Groundwater Outlet*.
Tag	-	The watercourse which the overland flow will discharge to.
Rain Gauge	-	The Storm used in the model simulation. In this case CDA_RCS_262_2014-2024 is the name for the continuous simulation time series used.
Outlet	-	The downstream major system node to which the subcatchment drains
Area	ha	The area is calculated internally by PCSWMM
Width / Flow Length	m	Flow path lengths for the subcatchments were identified based on the GIS flow path analysis and the longest length through the subcatchment selected as the flow path. The width is then internally calculated in PCSWMM from the flow path length and drainage area.
Slope	%	Averaged from the GIS analysis of the LiDAR surface data.
Imperv	%	Area weighted value from the SWMHYMO model parameters.
N Imperv	-	A constant of 0.013 is selected as the Manning's N for impervious surfaces such as roads.

Parameter	Units	Description
N Perv	-	A constant of 0.25 is selected as the Manning's N for pervious areas. The value is representative of light to tense turf land cover as per Table 3-5 of the EPA Storm Water Management Model Reference Manual Vol I – Hydrology (EPA, 2016).
DStore Imperv	mm	A constant of 1.57 mm is used as the impervious depression storage as per the City of Ottawa Sewer Design Guidelines 2012 Section 5.4.5.4.
DStore Perv	mm	A constant of 4.67 mm is used as the impervious depression storage as per the City of Ottawa Sewer Design Guidelines 2012 Section 5.4.5.4.
Zero Imperv	%	Used to represent areas where there is no depression storage in impervious areas such as water bodies. Not used in this model.
Subarea Routing	-	All catchments are completely drained to the outlet. The parameter would be used if any impervious areas were being drained via a storm sewer system.
Percent Routed	%	Used to determine the percent of sub-area being routed as per the parameter above. In this case 100% is going to the outlet.
Maximum Infiltration Rate	mm/hr	The maximum rate on the Horton Infiltration Curve, areas weighted from the infiltration rates provided by Paterson.
Minimum Infiltration Rate	mm/hr	The minimum rate on the Horton Infiltration Curve. This rate is based on the soil type assumed from the Paterson field testing.
Decay Constant	hr^{-1}	City of Ottawa standard value of 4.14 used.
Drying Time	days	The time for a fully saturated soil to completely dry is set at 7 days.
Maximum Volume	mm	The maximum volume of runoff which can be infiltrated and no limit has been applied in this model.
Infiltration Pattern		An infiltration pattern which provides for full infiltration in April to October, part infiltration March and November and no infiltration December to February was used.

Curb length, LID Controls and Erosion parameters are not used in the model. Curb length relates to pollution control, there are no LID controls in the pre development scenario and there is no application of soil sediment loss in the model.

2.0 SNOWMELT

Parameter	Units	Description
Dividing Temperature	°C	The temperature below which precipitation will fall as snow. Generally accepted as being 0°C. **Value: 0**
Snow Capture Factor	Fraction	It is assumed that the data from Environment Canada has captured all snowfall in the gauges. This factor can be used to increase snowfall where the gauges may not be accurate. **Value: 1.0**
ATI Weight	Fraction	Applied over the entire subwatershed, the ATI weighting factor is an indication of the thickness of the surface layer of snow. A low value will indicate a thicker surface layer with weighting to temperatures over the previous week while a value closer to 0.5 will indicate a normal surface layer. The lower the ATI Weight the snow will cool and warm more slowly. A value of 0.5 has been found to give reasonable results in watersheds and has been used here. **Value: 0.5**
Negative Melt Ratio	Fraction	The effect of the heat transfer during non-melt periods and the standard value is used. **Value 0.6**
Elevation above MS	m	The elevation will affect atmospheric pressure for the melt calculations. **Value: 107**
Latitude	°	The latitude will dictate the sunrise and sunset times in temperature calculations. **Value: 45.0**
Longitude Correction	minutes	Used to correct for in separation of the position of site versus the meridian of the standard time zone. This will have negligible effects. **Value: 0**

Parameter	Units	Description
Melt Coefficients	mm/hr/°C	The Melt Coefficient has been taken from the AES snowmelt equations for southern Ontario (MNR Technical Guide Flooding Hazard Limit, 2002). The AES equations have a melt coefficient of 3.66 mm/day/°C for mean daily air temperatures. This equates to 0.1525 mm/hr/°C. **Value: 0.153**
Base Temperature	°C	The base temperature at which the snowpack will melt has been assumed as 0°C. A lower value could be used for rooftops where there will be heat transfer through the roof. **Value: 0**
Fraction Free Water Capacity	Fraction	Since snow is considered a porous medium some of the melt water may be contained within the snow pack. The fraction of the free water capacity is the fraction of the snow pack void space which will retain meltwater. This fraction is normally less than 0.1 and 0.05 has been used here to represent a deep snowpack. A value of 0.25 may represent a shallow slush layer. **Value: 0.05**
Initial Snow Depth	mm	The initial snow depth on the site is considered as zero. **Value: 0**
Initial Free Water	mm	Since there is no initial snow depth the initial free water has also been considered as zero. **Value: 0**
Depth at 100% Cover	mm	The snowmelt model assumes that there will always be a depth of snow above which there will be 100% coverage of the snow, even in areas which may be affected by shading, drifting of topography. Typical depths are 25 mm to 100 mm. Since the area is relatively open with limited shading then the lower end of the value range has been used. **Value: 25**
Areal Depletion	Fraction	The areal depletion curve represents the area of snow cover for depths of the snow less than the depth at 100% coverage. Natural areal depletion curves are suggested by the software and are used here.

No parameters were used related to mechanical snow removal as it is assumed that there are no snow removal operations on the S1 Area currently.

3.0 GROUNDWATER

3.1 Groundwater Parameters

<table>
<tr><th>Parameter</th><th>Units</th><th>Description</th></tr>
<tr><td>Aquifer Name</td><td>-</td><td>Name of the aquifer representing soil conditions. Four Aquifers were created based on different soil conditions from OSG mapping. Only two of the aquifers are used within the study area.
<table>
<tr><th>Aquifer</th><th>Description</th><th>Clay content (%)</th><th>Sand content (%)</th></tr>
<tr><td>A</td><td>Sand</td><td>5</td><td>92</td></tr>
<tr><td>B</td><td>Sandy Loam</td><td>10</td><td>65</td></tr>
<tr><td>C</td><td>Sandy Clay Loam</td><td>28</td><td>60</td></tr>
<tr><td>D (not used)</td><td>Clay Loam</td><td>34</td><td>33</td></tr>
</table></td></tr>
<tr><td>Receiving Node</td><td>-</td><td>Name of the receiving node for groundwater outflow to baseflow. This is based on the groundwater subwatershed delineation.</td></tr>
<tr><td>Surface Elevation</td><td>m</td><td>Elevation of the ground surface for the subcatchment was averaged from the LiDAR surface.</td></tr>
<tr><td>Coefficients</td><td></td><td>The coefficients were set for the saturated groundwater zone to represent a storage reservoir where outflow is linear proportional to the water table depth without surface water interaction. It was considered that the nearest open water channels were sufficiently far to have negligible impact on groundwater levels. The groundwater equation used is:

$f_G = A1\ (d_L - h_{sw})$

Where:
f_G = groundwater flow
d_L = depth of the lower saturated subsurface zone
h_{sw} = height of surface water above the bottom of the groundwater zone
A1 = Calibration factor (estimated at 0.05)

Value: 0.5 and 1</td></tr>
</table>

Parameter	Units	Description
Surface Water Depth	m	Set as 0.5 metres to allow flow from the water table to surrounding watercourses. **Value: 0.5**
Initial Elevation and Threshold Water Table Elevation	m	Set as per the median groundwater contour provided by the Hydrogeological report. **Value: varies**
		All other parameters used as per the receiving node or aquifer

3.2 Aquifer Parameters

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Porosity</td><td>Fraction</td><td>The following values were used for the volumetric water content of the soil at saturation (i.e. volume of water per total volume):
<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Porosity</td><td>0.436</td><td>0.450</td><td>0.432</td><td>0.472</td></tr>
</table>
(Source: SPAW Calculator)</td></tr>
<tr><td>Wilting Point</td><td>Fraction</td><td>This is soil moisture contact at which plants cannot obtain sufficient moisture from the soil to meet transpiration requirements and they will die. It is roughly equivalent to the moisture content of soil at 15 atmospheres. The following values were used:
<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Wilting Point</td><td>0.050</td><td>0.081</td><td>0.183</td><td>0.213</td></tr>
</table>
(Source: SPAW Calculator)</td></tr>
<tr><td>Field Capacity</td><td>Fraction</td><td>Considered to be the amount of water a well-drained soil holds after free water has drained off. The following values were used:
<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Field Capacity</td><td>0.094</td><td>0.179</td><td>0.283</td><td>0.350</td></tr>
</table>
(Source: SPAW Calculator)</td></tr>
</table>

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Conductivity</td><td>mm/hr</td><td>Within the Aquifer Parameters, the soil saturated conductivity is a governing parameter of the percolation rate between the upper unsaturated soil layer and the lower saturated soil layer. This is not the same as any hydraulic conductivity used for the surface infiltration. The values have been selected from the SPAW calculator and are:
<table><tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr><tr><td>Conductivity (mm/hr)</td><td>114</td><td>50.3</td><td>7.8</td><td>4.6</td></tr></table>(Source: SPAW Calculator)</td></tr>
<tr><td>Conductivity Slope</td><td>-</td><td>Conductivity slope measures the rate at which a soil's hydraulic conductivity decreases with decreasing moisture content. Regression analysis has shown it can be estimated with the following relationship:
Conductivity Slope = 0.48(% Sand) + 0.85(% Clay)
Based on this relationship the following values were used:
<table><tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr><tr><td>Conductivity Slope</td><td>48</td><td>40</td><td>53</td><td>45</td></tr></table></td></tr>
<tr><td>Tension Slope</td><td></td><td>Used for backward compatibility in the software and not used in this model</td></tr>
<tr><td>Upper Evaporation Factor</td><td>Fraction</td><td>This factor determines the fraction of available subsurface evaporation rate used in the upper subsurface zone (compared to the lower subsurface zone). A higher evaporation rate is associated with looser soils, lower water table elevations and shallow root zones. It was assumed that in all soils 80% of the available subsurface evaporation would be used in the upper zone due to the depth of the water table.
Value: 0.8</td></tr>
<tr><td>Lower Evaporative Depth</td><td>m</td><td>The depth of the lower subsurface zone which can be used for evapotranspiration should be approximate to the expected average depth of root penetration. The following values were used:
<table><tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr><tr><td>Evaporative Depth (m)</td><td>1.5</td><td>2.4</td><td>3.0</td><td>5.2</td></tr></table>(Source: Shah et al 2007 from EPA 2015)</td></tr>
</table>

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Lower Groundwater Loss Rate</td><td>mm/hr</td><td>This is the rate of percolation from the lower subsurface zone to a deep aquifer and is approximate to the rate at which the water table elevation will drop over a prolonged dry period. The saturated hydraulic conductivity of a compacted clay soil was used in all cases.
Value: 0.004</td></tr>
<tr><td>Bottom Elevation</td><td>m</td><td>The elevation of the bedrock as averaged from the Patterson 2016 report.
Value: 85</td></tr>
<tr><td>Unsaturated Zone Moisture</td><td></td><td>The moisture content of the unsaturated upper subsurface zone at the start of the simulation. Cannot be less than the wilting point and cannot be more that porosity. Assumed to be an approximate value between the wilting point and porosity fractions.
<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Evaporative Depth (m)</td><td>0.25</td><td>0.22</td><td>0.32</td><td>0.35</td></tr>
</table>
</td></tr>
</table>

Horton Equation

One of the oldest and most widely used infiltration equations was developed by Horton (1939). This equation was used in this study to compare the measured equation parameters with published literature values. The equation is as follows:

$$f = f_c + (f_o - f_c)e^{-kt} \quad (1\text{-}1)$$

where:
f= infiltration capacity (in/hr),
f_o = initial infiltration capacity (in/hr),
f_c = final infiltration capacity (in/hr),
k = empirical constant (hr^{-1})

This equation assumes that the rainfall intensity is greater than the infiltration capacity at all times and that the infiltration rate decreases with time (Bedient and Huber 1992). The capacity of the soil decreases as the time of the storm increases because the pores in the soil become saturated with water and do not allow water to continuously infiltrate through the surface (Bedient and Huber 1992). The Horton equation's major drawback is that it does not consider storage availability in the soil after varying amounts of infiltration have occurred, but only considers infiltration as a function of time (Akan 1993).

It is recommended that f_c, f_o, and k all be obtained through field data, but they are rarely measured locally. More commonly, they are determined through calibration of relatively complex stormwater drainage models, or by using values published in the literature. The use of published values in place of reliable field data is the cause of much concern by many (Akan 1993). The following lists include commonly used Horton infiltration parameter values:

Soil Type	f_o (in/hr)
Dry sandy soils with little to no vegetation	5
Dry loam soils with little to no vegetation	3
Dry clay soils with little to no vegetation	1
Dry sandy soils with dense vegetation	10
Dry loam soils with dense vegetation	6
Dry clay soils with dense vegetation	2
Moist sandy soils with little to no vegetation	1.7
Moist loam soils with little to no vegetation	1
Moist clay soils with little to no vegetation	0.3
Moist sandy soils with dense vegetation	3.3
Moist loam soils with dense vegetation	2
Moist clay soils with dense vegetation	0.7

Soil Type	f_c mm/hr	(in/hr)	k (1/min)
Clay loam, silty clay loams	0–1.3	(0–0.05)	0.069
Sandy clay loam	1.3–3.8	(0.05–0.15)	0.069
Silt loam, loam	3.8–7.6	(0.15–0.30)	0.069
Sand, loamy sand, sandy loams	7.6–11.4	(0.30–0.45)	0.069

Source: Akan 1993.

The above k values are not divided into categories, with only a single value used for all conditions (Akan 1993). The units of the k value are listed as 1/min instead of 1/hr because the time steps commonly used in urban hydrology are measured in minutes, while the infiltration rates are commonly measured in units of inches per hour. These values will be compared to the measured values obtained during this study by calibrating the Horton equation.

Master Servicing Study

Barrhaven South Urban Expansion Area

Greenbank Road, Ottawa

J.L.Richards
ENGINEERS · ARCHITECTS · PLANNERS

Executive Summary

Minto Communities Inc. (Minto) and Mattamy Homes Ltd. (Mattamy) herein referred to as the Sponsored Owner, have retained a Consultant Team to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA), which will be implemented as an Amendment to the City of Ottawa (City) Official Plan (OP). J.L. Richards & Associates Limited (JLR) has been retained to undertake the Master Servicing Study (MSS) Class Environmental Assessment (Class EA) that would outline water, wastewater, storm and stormwater management servicing strategies for the BSUEA. The following report documents the reviews, analyses and findings meant to outline the preferred infrastructure servicing strategies for the BSUEA Community Design Plan (CDP). The specific objectives of this report were set out in the Terms of Reference (Appendix A) and outlined as follows:

- Review and inventory the existing infrastructure surrounding the proposed development;
- Estimate residual capacity of the existing infrastructure;
- Develop a set of feasible alternatives for storm, sanitary and water services for the proposed development based on the preferred CDP;
- Evaluate the feasible service designs based on a set of criteria that incorporates environmental, social and fiscal considerations; and
- Select one, or set of, optimal service option(s) and provide criteria for a detailed design.

This MSS has been prepared to support the Community Design Plan (CDP) for the Barrhaven South Urban Expansion Area (BSUEA). It provides a functional design solution for on-site storm drainage, wastewater collection and water distribution servicing in the BSUEA. Future Plan of Subdivision development applications under the Planning Act will build upon and refine the solutions presented herein. The Master Servicing Study is an integral part of the CDP study process and is undertaken to confirm the feasibility of servicing a potential development site. This document has also been prepared to meet the requirements of the provincial planning and Class Environmental Act (Class EA) processes.

The BSUEA is 121 ha of land bounded by Cambrian Road to the north and Barnsdale Road to the south. The expansion area is adjacent to the current City of Ottawa Urban Boundary limits and approximately 360 m east of Borrisokane Road. The subject site is an undeveloped mix of former agricultural land and forested areas and contains two (2) ongoing aggregate extraction operations. The southern portion of the site generally consists of former agricultural land with some woodlot areas.

Opportunities were identified and a number of alternative servicing options were developed and evaluated using a set of criteria that accounted for environmental, social and economic impacts. High level servicing strategies for storm, sanitary and water infrastructure systems are outlined within the MSS document. These strategies have been developed to expand and upgrade the existing and planned municipal infrastructure to achieve the land use objectives, while minimizing impacts to the social and natural environments. The recommended strategies are summarized below:

- The design of the storm drainage system has been undertaken using the dual-drainage approach.

- Two (2) separate storm servicing solutions were developed; one conventional servicing strategy and one that incorporates the Etobicoke Exfiltration System (EES). Should the performance of Phase 1's EES be inconclusive, then the feasibility of an infiltration gallery servicing the Phase 2 lands was reviewed. The high level assessment found that an infiltration gallery incorporated within the proposed spill-over dry pond next to Barnsdale Road could provide sufficient storage for part of Minto's Phase 2 lands.
- The stormwater management solution incorporates potentially four (4) stormwater management ponds; two (2) adjacent to Greenbank Road, one spill-over dry pond west of the CDP boundary and a potential spill-over dry pond within the Mattamy West Lands. An additional two (2) potential stormwater management facilities have been identified in the stormwater management solution for the aggregate extraction areas.
- The residual capacities in the surrounding wastewater services were assessed to determine viable servicing outlets for wastewater generated within the BSUEA.
- The existing constructed and planned wastewater system network can provide servicing for the BSUEA.
- Upsizing of some planned (but currently unconstructed) wastewater infrastructure is recommended.
- The MSS servicing evaluation has identified that wastewater servicing for the BSUEA is feasible based on the downstream residual capacities and the proposed trunk sanitary sewer network.
- The BSUEA can be serviced from the BARR pressure zone with watermain extensions from the surrounding existing watermains.
- The analysis confirmed that there are no upgrades to the planned distribution network identified in the 2013 Infrastructure Master Plan.

The MSS sets out the design criteria for future draft plan and site plan applications within the BSUEA. The design criteria for storm, wastewater and water are consistent with current design standards. The MSS component of the BSUEA CDP has been developed to satisfy the requirements of Phases 1 and 2 of the Municipal Class EA process. Infrastructure projects that will be undertaken as part of the development of the BSUEA, along with their phasing and schedule classification, are contained within the report.

The MSS demonstrates that the development proposed by the CDP can be serviced by extending existing municipal water and wastewater infrastructure; upsizing planned future wastewater infrastructure, and constructing stormwater management facilities.

Table of Contents

Executive Summary i
1.0 Introduction 1
1.1 Barrhaven South Urban Expansion Area 1

1.0 Introduction

Minto Communities Inc. (Minto) and Mattamy Homes Ltd. (Mattamy) herein referred to as the Sponsored Owner, have retained a Consultant Team to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA), which will be implemented as an Amendment to the City of Ottawa (City) Official Plan (OP). J.L. Richards & Associates Limited (JLR) has been retained to undertake the Master Servicing Study (MSS) Class Environmental Assessment (Class EA) that would outline water, wastewater, storm and stormwater management servicing strategies for the BSUEA. The following report documents the reviews, analyses and findings meant to outline the preferred infrastructure servicing strategies for the BSUEA Community Design Plan (CDP). The specific objectives of this report were set out in the Terms of Reference (Appendix A) and e outlined as follows:

- Review and inventory the existing infrastructure surrounding the proposed development;
- Estimate residual capacity of the existing infrastructure;
- Develop a set of feasible alternatives for storm, sanitary and water services for the proposed development based on the preferred CDP;
- Evaluate the feasible service designs based on a set of criteria that incorporates environmental, social and fiscal considerations; and
- Select one, or set of, optimal service option(s) and provide criteria for a detailed design.

1.1 Barrhaven South Urban Expansion Area

The BSUEA is 121 ha of land bounded by Cambrian Road to the north and Barnsdale Road to the south. The expansion area, as shown on Figure 1-1, is adjacent to the current City of Ottawa Urban Boundary limits and approximately 360 m east of Borrisokane Road. The subject site is an undeveloped mix of former agricultural land and forested areas and contains two (2) ongoing aggregate extraction operations. The southern portion of the site generally consists of former agricultural land with some woodlot areas.

1.2 Class Environmental Assessment Process

The *Ontario Environmental Assessment Act* (EA Act), enacted in 1976, formally recognizes the Municipal Class EA process and outlines requirements for EA approval. The Class EA applies to municipal infrastructure projects including roads, water, wastewater and stormwater projects. To ensure that environmental impacts and effects are considered for each project as per the EA Act, proponents are required to generally follow the planning process set out in the Class EA Guidelines, prepared by the Municipal Engineers Association (MEA, 2011). The Class EA process includes the following stages:

- Phase 1: Problem or opportunity identification.
- Phase 2: Identification and evaluation of alternative solutions to determine a preferred solution to the problem or opportunity. This Phase also compiles an environmental 'inventory', identifies impacts, and outlines mitigation measures.

CHECKED: HM	

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\GIS\26610 C LOCATION PLAN.DWG

PLOT DATE: September 11, 2017 3:18:27 PM

- Phase 3: Identification and evaluation of design concepts for the preferred solution. A detailed evaluation of the environmental effects and mitigation measures will be addressed during this project Phase.
- Phase 4: Complete and place Environmental Study Report (ESR) on Public Record. The Report will document Phases 1 through 3 and summarize the consultation undertaken throughout the planning process and is considered valid for a 10 year period.
- Phase 5: Implementation and monitoring.

Since projects may vary with regards to their environmental impact, they are classified in terms of the following schedules:

- Schedule 'A' projects usually have minimal environmental effects and generally include normal or emergency operational and maintenance activities. These projects are pre-approved under the Class EA planning process. Projects within this category are subject to Phases 1 and 5.
- Schedule 'B' projects have potential for some adverse environmental impacts and, therefore, the proponent is required to proceed through a screening process, including consultation with affected parties. Generally, these projects include improvements and minor expansions to existing facilities. Projects within this category are subject to Phases 1, 2 and 5.
- Schedule 'C' projects have potential for greater environmental impacts and are subject to all five (5) Class EA Phases. Generally, these projects include the construction of new facilities and major expansions to existing facilities.

Based on the MEA Guidelines, this project has been undertaken as a Schedule 'B' Class EA, and thus Phases 1 to 2 of the Class EA process were completed and summarized herein.

1.3 Integrated Planning Process

In 2009, the City of Ottawa Council and the Municipal Board reviewed the City's OP and designated a number of expansion areas for future development, including the BSUEA. These urban expansion areas are intended to accommodate the projected population growth to 2031. In order to ensure the development of functional and livable neighborhoods, an integrated planning approach is utilized. The integrated approach consists of drawing information from a number of detailed studies (summarized below) in order to inform and guide the planning process for the development of these new communities.

- Community Design Plan (CDP): Transmits the guiding principles of the City's OP down to a community scale. The CDP outlines various infrastructure requirements such as roads, sanitary, storm and water services. The CDP also establishes the responsibilities between owners and the City with regards to new infrastructure projects.
- Transportation Master Plan (TMP): Inventories existing transportation facilities and outlines future transportation requirements.
- Master Servicing Study (MSS): Provides high level analysis of different service options for storm, sanitary and water distribution systems based on existing conditions and projected future demand. Provides design guidelines and criteria for further detailed design.

- Environmental Management Plan (EMP): Studies potential adverse effect of proposed land-use changes and develops a plan to minimize them.

The Integrated Approach combines the CDP with a Class EA. In doing so, the approval requirements for both the EA and the Planning Act are able to be coordinated.

1.4 Study Team and Agency Involvement

The organization of the CDP and preparation of the individual MSS documents is a collaborative effort between various stakeholders, the general public, and members of both the Core Project Team (CPT) and Technical Advisory Committee (TAC). These committees included several groups within the City of Ottawa organization, provincial government agencies, the Owner, and a consortium of consultants.

1.4.1 Core Project Team (CPT)

The CPT was established at the onset of the study, and was comprised of various groups at the City of Ottawa (including internal project management) and representatives from the Planning, Infrastructure & Economic Development Department portfolio, complemented by staff from other departments. Other members included the two (2) participating sponsoring Landowners (Minto and Mattamy), and the Consulting Team that consisted of the following firms:

- FOTENN Planning + Design - Land Use Planning and Urban Design;
- Morrison Hershfield - Integrated Environmental Assessment and Environmental Management Plan;
- J.L. Richards & Associates Limited - Master Servicing Study;
- Stantec Inc. - Transportation Master Study;
- Dillon Consulting Limited - Natural Heritage;
- Paterson Group - Geotechnical and Hydrogeology; and
- Golder Associates Ltd - Archaeology and Heritage.

1.4.2 Technical Advisory Committee (TAC)

The TAC was established to discuss the various CDP alternatives, provide guidance for the preparation of the EMP, and the Transportation and Master Servicing Plans. Representatives of the following organizations were invited to participate:

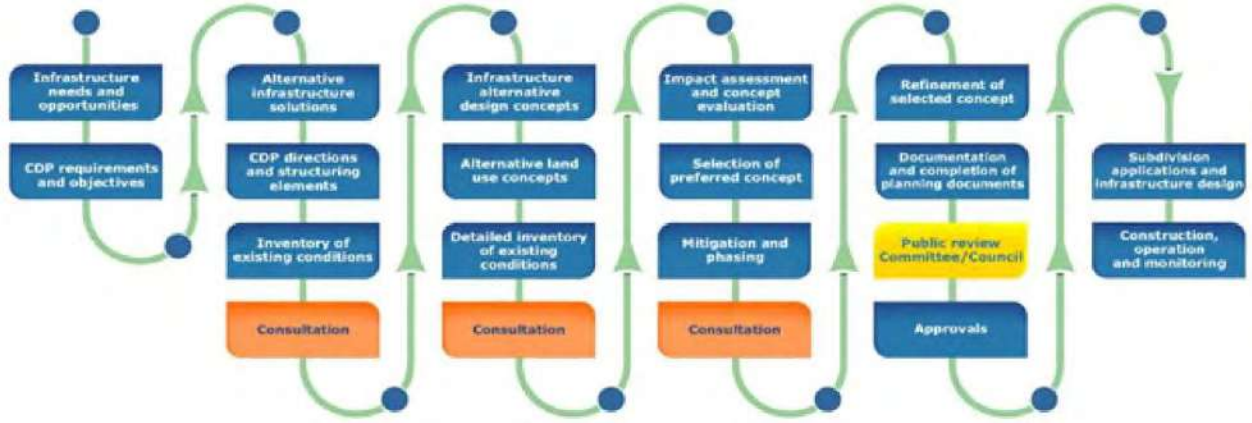
- CPT Members (as needed);
- City of Ottawa Economic Development Services;
- City of Ottawa Transportation Planning;
- City of Ottawa Parks Forestry & Stormwater Services;
- City of Ottawa Transit Customer Services and Planning;

- City of Ottawa Parks and Facilities Planning Services;
- City of Ottawa Infrastructure Services;
- City of Ottawa Planning Services;
- City of Ottawa Right of Way Heritage & Urban Design Services;
- Ottawa Public Health;
- Ottawa Carleton District School Board (OCDSB);
- Conseil des écoles publiques de l'Est de l'Ontario (CEPEO);
- Ottawa Catholic School Board (OCSB); and
- Hydro Ottawa.

2.0 Master Servicing Study Process

The Master Servicing study is an integral part of the CDP study process and is undertaken in order to confirm the feasibility of servicing a potential development site. It is integrated with the provincial planning and Class EA processes. Collaboration with stakeholders and the general public was an integral part of CDP study process, consequently, a series of Public Consultation events were held to fulfill the Class EA requirements. The flow chart presented in Figure 2-1, prepared by Morrison Hershfield, shows the integration of the Class EA, CDP and OP amendment processes.

Figure 2-1: Integration of the Class EA, CDP and Official Plan Amendment Processes[1]



Initially, a review of the existing services was carried out to establish residual capacity in in the infrastructure for the flows that will be generated by the BSUEA. The site's physical features - including soil properties, existing watercourse and aquatic features - were also inventoried through site investigations conducted as part of an EMP.

2.1 Public consultation

As shown in Figure 2-1, a minimum of three (3) planned consultation events are to be held as per the Integrated CDP and Class EA processes. The consultations undertaken for this study are summarized below:

2.1.1 Public Consultation Event No. 1 (March 10, 2016)

This Open House was the first of the scheduled public consultation meetings, held at the Pierre-Savard French Catholic High School. Here, residents in the vicinity of the Study Area were invited to attend and discuss the future CDP for the BSUEA. Prior to the identification of the infrastructure needs that would support this CDP, characterization of the Existing Conditions was completed by the consortium of consultants. Public Consultation Event No. 1 was intended to share the information that was gathered and compiled for landform, soil and geology, surface water, existing infrastructure in the vicinity of the Study Area limits, groundwater

[1] Courtesy of Morrison Hershfield

resources, aquatic and fish habitat, wetlands, terrestrial vegetation, potential Species at Risk, and wildlife.

2.1.2 Public Consultation Event No. 2 (November 5, 2016)

This second public consultation meeting was held as a workshop at the Pierre-Savard French Catholic High School. The attendees were assigned to four (4) facilitated groups and asked to develop their own version of the CDP while considering land use constraints and opportunities, which have been identified in the Existing Condition Reports. They were also asked to identify their preferred locations of residential and commercial areas, collector roads, schools, parks, library, Park and Ride, and stormwater management facilities (SWMFs). Four (4) CDPs were developed for further consideration and analysis by the consortium of Consultants and members of the TAC.

2.1.3 Public Consultation Event No. 3 (June 22, 2017)

This third public consultation meeting was scheduled to present the preferred land use concept plan, to collect feedback from the community, and to provide a summary of next steps. In addition, supporting studies and anticipated servicing and transportation projects were identified.

2.1.4 On-Site Meeting (Municipal Drains)

As part of the surface water component summarized in the Existing Condition Report (Appendix B), the BSUEA was found to span over three (3) separate watersheds / sub-watersheds: the Jock River, the Rideau River via the Hawley/Hawkins Municipal Drain, and Mud Creek via the Thomas Baxter Municipal Drain. As per the requirements of the Drainage Act (Section 78, Chapter D.17, R.S.O. 1990), any modifications to the hydrological regime must be documented in an Engineers Report for either of the above-noted Municipal Drains. Based on the requirements of the Drainage Act, the update to the Engineers Report is to be completed by an Engineer of Record. As a result, City council appointed on July 13, 2016, Andy Robinson P.Eng., of Robinson Consultants Inc., as the Engineer of Record to document and address modifications to the Engineers Report for the above-noted Municipal Drains.

As per the requirements of the Drainage Act, an on-site meeting was completed at the North Gower SCS (2155 Roger Stevens Drive) on February 15, 2017 for both the Thomas Baxter and Hawkins Municipal Drains. Pending the recommended storm servicing alternative for the BSUEA, additional public consultations may be held.

3.0 Existing Conditions

The existing site conditions were identified and outlined within the BSUEA by JLR as part of an Existing Conditions Report (Appendix B). The document includes information that pertains to the site's climate, geology, physiography, drainage, surficial geology, bedrock, aquifer systems and groundwater levels, existing/planned infrastructure at the subject site's boundary as well as additional physical attributes of the site. The latest version of this Report (September, 2017) is appended to this document in Appendix B.

3.1 Site Location

The BSUEA CDP consists of 121 ha of land bounded by Cambrian Road to the north and Barnsdale Road to the south. The BSUEA is located immediately west of the current City of Ottawa Urban Boundary and approximately 360 m east of Borrisokane Road as depicted in Figure 3-1.

The subject site is an undeveloped mix of former agricultural land and forested areas, spread generally across the southern portion of the site. Also within the site boundary are two (2) ongoing aggregate extraction operations. These pits are located in the northern area of the site, extending west to the Borrisokane Road / Highway 416 corridor. Woodlots and pasture areas are adjacent to the site to the north, and recent urban development abuts the eastern boundary. The topography across the site has significant undulations, and there is a knoll located approximately 1 km north of Barnsdale Road. At the intersection of Borrisokane Road and Barnsdale Road, southwest of the site, there is an existing waterbody that appears to be man-made.

3.2 Surface Water Characteristics and Receiving Watercourses

Based on LiDAR data and the topographical survey compiled by Stantec (Geomatics), the BSUEA is tributary to three (3) sub-watersheds, as depicted on Figure 3-1: the Jock River, the Rideau River via the Hawley/Hawkins Municipal Drain, and Mud Creek via the Thomas Baxter Municipal Drain. On-site investigations completed by the team's biologist did not identify any watercourse or formal conveyance channels within the BSUEA. The absence of channels or formal watercourses was confirmed by the LiDAR data, and is generally indicative of areas exhibiting particularly low surface runoff potential.

Catchment areas within the BSUEA have been delineated based on LiDAR data as well as surface infrastructure such as roads (which tend to form a drainage path barrier) and culverts (where flow will concentrate into a point source). Thirteen (13) culvert crossings were inventoried in close proximity to the subject area for which eleven (11) are shown on Figure 3-1 and two (2) are located across Cambrian Road to the north of the BSUEA. In Figure 3-1 three (3) culverts are along the south side of Barnsdale Road (south of BSUEA) and the remaining eight (8) culverts provide conveyance across access routes to property and farmland along Borrisokane Road and Barnsdale Road.

3.3 Geotechnical

The site consists primarily of glacio-fluvial deposits to the north and reworked glacio-fluvial sand deposits to the west and southwest. Overburden thickness was found to generally range between 10 m and 17 m. Geological mapping from Natural Resources Canada (NRCan) shows that the bedrock in the area consists of dolomite of the Oxford formation.

3.4 Site Hydrology and Hydraulics

A SWMHYMO hydrological model was developed for the BSUEA (refer to Appendix B) to estimate flood flows at the boundary control points of the site for storm events ranging from the 1:2 year to the 1:100 year recurrence. The model was developed based on the land use, soil characteristics, types of flow paths, and topography of the site. The simulated area included the BSUEA, as well as the lands up to the external boundary points: Cambrian Road, Borrisokane Road and Barnsdale Road.

The SWMHYMO model results show relatively low flow rates at each of the culverts, due to the high infiltration capacity of the soils in the area and the low imperviousness. In general, during larger and infrequent events, runoff will increase as the infiltration capacity decreases due to saturation of the soils. Section B5.6 of the Existing Condition Report (Appendix B) summarizes the simulation results at each of the culverts.

The water budget of a given area is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. The analysis of the water budget is often carried out to establish the baseline condition and to assess any future changes in infiltration to subsurface water-bearing zones and, consequently, to surface runoff resulting from a significant land cover modification such as urbanization. It is also used to predict changes to the hydrological cycle that will result from urbanization of lands.

An understanding of the water budget within a given study area can be gained through the use of a continuous hydrological model. The PCSWMM software platform was used for this study, which includes simplified groundwater and snowmelt modules that allow continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall and snowmelt.

A long-term simulation was carried out for the site based on 30 years of hourly precipitation and temperature. The long-term simulation results indicate that infiltration accounts for approximately 40% of the total average annual precipitation of 844 mm. On average, runoff accounts for only 1 mm out of the total annual precipitation of 844 mm per year, representing approximately 0.1%. Section B6.1.5 of the Existing Condition Report (Appendix B) summarizes the findings of the water budget analysis.

The Barrhaven South Community (BSC) bounded by the Jock River to the north, Borrisokane Road to the west and by existing Greenbank to the east is to be serviced by five (5) existing or planned stormwater management facilities (SWMFs). Two (2) SWMFs, known as the Corrigan Pond and the Todd Pond, are currently in operation. Three (3) additional SWMFs are planned to service the BSC in accordance with the Jock River Subwatershed Study, the Barrhaven South

Master Servicing Study and the Barrhaven South Master Servicing Study Addendum. These planned SWMFs are referred to as the Clarke Pond, the Greenbank Pond and the Borrisokane (formerly Cedarview) Pond. Although all five (5) existing/planned SWMFs in Barrhaven South have excess water quality volumes and have available residual capacity in their associated trunk infrastructure, all existing and planned storm sewer systems in Barrhaven South have relatively high hydraulic grade line (HGL) elevations. Areas tributary to the Corrigan and Todd ponds also have major system ponding depth that are generally at or exceeding the maximum allowable depth of 350 mm.

3.5 Aggregate Extraction Pits

As previously noted, the BSUEA includes two (2) aggregate extraction pits, which are contiguous properties. The southern property is the Brazeau Todd Pit (Brazeau), while the northern property is the Drummond Costello Pit (Drummond). Since both properties have a current Class 'A' license, their operation is in accordance with the Ontario Aggregate Resources Act and Regulations. Information regarding the limit of extraction, license boundary groundwater elevation and anticipated rehabilitation elevation dates to 1992 and has been included in Appendix C. Key information for both properties has been extracted (from the 1992 information) and is summarized in Table 3-1 below.

Table 3-1: Aggregate Extraction Pits Summary

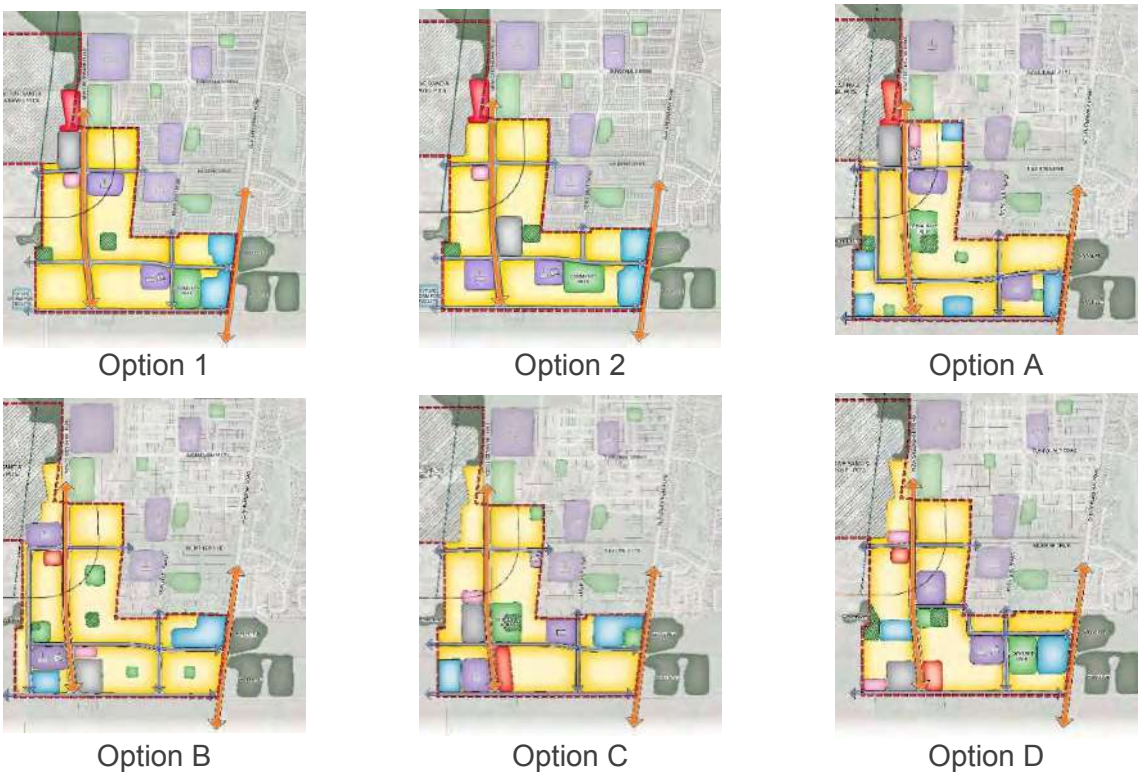
Design Information	Brazeau Pit	Drummond Pit
Licensed Area	40.2 ha	23.5 ha
Area of Operation	38.1 ha	22.3 ha
Existing Disturbed Area	40.2 ha	16.4 m
Minimum Rehabilitation Elevation	97.0 m	104.0 m

4.0 Evaluation of Servicing Alternatives

4.1 Alternative Demonstration Plans

A total of six (6) alternative CDPs were developed for the BSUEA: two (2) CDPs were developed by the sponsored Owner (Options 1 and 2), and four (4) CDPs were developed by the public as part of the second Public Open House held on November 5, 2016 (Section 2.1, Options A to D). The six (6) CDP alternatives are shown in Figure 4-1.

Figure 4-1: Alternative Demonstration Plans



The servicing of these six (6) alternative CDPs was addressed at a high level as part of the evaluation of these alternatives. The high level servicing concepts developed for each alternative demonstration plan had to meet City and Provincial Standards and Guidelines. In parallel, evaluation of the CDPs was undertaken in terms of the environment, social connections, transportation linkages, and economics.

The elements reviewed as part of the servicing evaluation criteria for the proposed CDPs included: opportunities for infiltration; compatibility with existing and future municipal infrastructure; maintenance and operations requirements associated with SWMFs; minimization of upgrades to the water system; and construction and operation requirements for the sanitary system.

The evaluation identified four (4) levels of impact for each of the criteria as summarized in Table 4-1. In the overall evaluation, Option 1 was identified as the most preferred option as it achieved

the highest scoring with Option A and Option 2 next to Option 1. This was consistent with the servicing evaluation results.

Table 4-1: Impact Description Table

Definition of Impact	Negative Impacts	Positive Impacts (Benefits)	
The impact exists, but is of a magnitude small enough that it has little effect, or is of limited benefit; or has the least impact compared to all the alternatives. Best compliance, contribution or benefit.	Negligible	Greatest	Most Preferred ■
The impact exists and is of relatively small physical magnitude or duration. Provides a moderate effect or contribution or benefit.	Minor	Good	◘
The impact exists and has an effect that is of a physically larger magnitude or prolonged duration. Provides a measurable contribution or benefit.	Some	Reasonable	▣
The impact exists and has an effect that is relatively large, permanent or has the most impact when compared to other alternatives. Little to no contribution or benefit	Major	Limited	Least Preferred □

4.2 Evaluation of Servicing Criteria / Objectives

4.2.1 Opportunities for Infiltration

Achieving distributed infiltration is driven by two (2) key factors; i) having soil that is conducive to infiltration, and ii) achieving infiltration when native soils have a separation with the groundwater table. With respect to key factor (i), measured saturated field hydraulic conductivities showed that infiltration rates across the BSUEA are conducive to achieving groundwater recharge (refer to Section B6.1.1 of the Existing Condition Report, Appendix B). With respect to key factor (ii), the distance between the top of the overburden to the measured groundwater level is generally greater than 5 m across the BSUEA, with the exception of the southeast portion of the site that abuts Greenbank Road. In that area, the distance between the top of the overburden to the groundwater level was measured to be as low as 3.5 m – 4.5 m. As a result, promoting distributed infiltration near Greenbank Road (from Barnsdale Road to Quinn's Pointe) would be difficult to achieve as the performance of the infiltration system would be impacted by the high groundwater levels. Based on this assessment, placing stormwater management facilities in the area in close proximity to Greenbank Road would score the highest, as there would not be any need to infiltrate in that area. Consequently, Options 1 and 2 scored the highest, while Options A to D scored the lowest.

4.2.2 Compatibility with Existing Infrastructure

In all of the alternatives, with the exception of Option D, there is a proposed East-West Collector Road that provides the greatest benefit for the alignment of trunk infrastructure. Option D would place a greater portion of the trunk network on local roads and limit direct connections between existing and proposed trunk infrastructure.

Options 1, 2 and A to C were rated as most preferred under this criteria while Option D was the least preferred.

4.2.3 Stormwater Management Construction and Maintenance Requirements

Currently, municipal and provincial standards require that the control of urban runoff is achieved in regional end-of-pipe facilities sized to provide the necessary quantity and quality control. Quantity control is necessary on this site due to the limited residual capacity in the existing storm sewer systems. Proposed end-of-pipe SWMFs can be located as efficiently as possible within the layouts proposed in the CDPs to reduce construction and maintenance costs. The facilities should be placed in areas of low topography to capture the largest drainage area as possible. Fewer, larger facilities are preferred over a larger number of smaller facilities. This will provide savings in both construction and maintenance costs in the future and provides for a more efficient use of land that must be dedicated to stormwater management.

There is currently a spill-over dry pond located on the western side of Greenbank Road. This facility provides major overland flow control from the existing Quinn's Pointe subdivision located to the north of the CDP area. The intent is to decommission and replace the spill-over dry pond with a SWMF at the same location to control major system flows. This proposed facility would also intercept the existing minor system flows from Quinn's Pointe. This strategy provides for greater residual capacity in the receiving trunk storm sewer along Greenbank Road.

Options 1 and 2 have similar stormwater management arrangements: two (2) end-of-pipe facilities on the eastern boundary with Greenbank Road, at the low point of the area, as well as a spill-over dry pond on the western boundary, outside of the CDP. The latter facility is of lesser complexity as it does not have any inlet sewers and simply provides for control of major system flows east of New Greenbank Road, as City standards prohibit major system flows being conveyed across urban arterials.

Option A has five (5) SWMFs that are not always located in areas of low topography. As a result, land utilization will not be maximized and the areas serviced by some of the facilities would be limited. In addition, Option A does not include a facility that would replace the current spill-over dry pond servicing the existing Quinn's Pointe subdivision.

Options B and C have two (2) SWMFs that are both in areas of low topography. One of the facilities will provide control for Quinn's Pointe, and the other is west of

New Greenbank Road. As a result, overland flows do not have to cross New Greenbank Road or existing Greenbank Road. The single eastern facility may be significantly larger than the facility required under Options 1 and 2, while the western pond block may be too large due to its small drainage area.

Option D has two (2) facilities. However, neither is located in areas of low topography, and nor do they provide control for the overland flow from Quinn's Pointe.

From a stormwater management perspective, Options B and C were identified as having the greatest positive impacts. Options 1 and 2 have good positive impacts, Option D has reasonable impacts, and Option A is the least preferred CDP option.

4.2.4 Water System Upgrade Requirements

The BSUEA has a number of areas with high topography (elevations greater than 110 m) south of the Brazeau aggregate extraction property. Pressures in the proposed distribution system in these areas will, therefore, be lower. Since standards required that a minimum pressure criterion be achieved, CDPs developed with non-residential land uses located in the areas of higher topography are preferred as this will reduce the potential for additional pumping to mitigate low distribution system pressures.

Option 1 and Option A include the Park and Ride, as well as commercial land uses, as part of the potential low pressure zones. Consequently, Option 1 and Option A have the greatest positive impacts, based on the location of the non-residential uses. The other alternatives have greater areas of residential uses in the potential low pressure zones and, therefore, have the potential to require additional water supply infrastructure to meet standard pressure criteria.

4.2.5 Sanitary Servicing Construction and Operation Requirements

Sanitary servicing of residential properties generally requires deeper sewers than for non-residential uses to service the basements. When approaching the Brazeau property, topography increases up to elevation 111.0. However, the Brazeau property has a rehabilitation elevation of 97.0 m (refer to Table 3-1), which is 4 m above. As a result, planning for residential usage with deep sanitary sewers next to the Brazeau property will be more challenging due to this grade differential and will require special attention by the designers. Consequently, having land uses – such as commercial blocks or Park and Ride blocks that do not require basement connections next to the Brazeau property—would be preferred.

Options 1 and 2 and Option A have commercial and Park and Ride blocks next to the Brazeau property. Consequently, these options are the most preferred, while Options B to D are the least preferred due to difficulty with sanitary servicing of their residential land uses next to the Brazeau property.

4.3 Preferred Demonstration Plan and Servicing Blocks

Based on a rigorous evaluation of all contributing elements, including servicing, environmental and transportation, as well as the comments received from the Public Open House, Option 1 was selected as the preferred CDP. Feedback from the Open House resulted in minor amendments to Option 1, from which a demonstration plan was developed. The final demonstration plan used to develop this MSS is shown in Figure 4-2.

For discussion purposes, the demonstration plan has been broken down into the following five (5) areas (Figure 4-2) for the purpose of assessing the performance of the proposed servicing:

- **Minto Lands** – Extends from the eastern to the western boundaries of the BSUEA, from Barnsdale Road to the Kilbirnie Drive Extension, including the lots facing Kilbirnie Drive. For servicing purposes, this sector also includes the commercial block at the intersection of Kilbirnie Drive and New Greenbank Road, although the land owner is Mattamy for part of this future block.
- **Mattamy Lands East** – Within the BSUEA, from north of the Kilbirnie Drive extension, between New Greenbank Road and the current urban boundary limit, and part of the Mattamy Half Moon Bay South development. The servicing design for this development was carried out by others.
- **Mattamy Lands West** – Includes the proposed residential area immediately west of New Greenbank Road and north of the proposed commercial block.
- **Brazeau Aggregate Extraction Area** – Extends from the Kilbirnie Drive extension to the potential Dundonald Drive extension from the commercial block, and BSUEA Mattamy Lands West to the western boundary of the CDP.
- **Drummond Aggregate Extraction Area** – Extends from the Dundonald Drive extension to the northern limit of the CDP and from the western to the eastern limits of the CDP.

5.0 Storm Drainage and Servicing

5.1 Background

A stormwater management strategy needs to be developed to ensure that runoff from the site meets the necessary provincial and municipal requirements. The adopted strategy must also respect the integrity of the downstream systems from both a minor and major system perspective. The stormwater management strategy should identify lot level measures, SWMFs in terms of size and location, major overland flow paths and storm sewer networks. As noted in Section 3.3, the study area is located across three (3) watershed catchments: the Jock River catchment to the north, Rideau River catchment to the east, and Mud Creek catchment to the south (Figure 3-1). However, surface flow from the BSUEA lands is not directly connected to any of these watercourses.

The study area is located on the edge of the current urban boundary and has existing or planned development on its eastern boundary. The urban areas adjoining the BSUEA are currently serviced, or planned to be serviced, by SWMFs which were identified as part of the stormwater management strategy to service the BSC, located to the north of the BSUEA. The Draft 2014 BSMSSA (Stantec) identified a preferred stormwater management strategy for the BSC, which was also in accordance with the Jock River Reach One Subwatershed Study (Stantec, 2007). The five (5) SWMFs servicing the South Barrhaven area are the Corrigan, Todd, Borrisokane (formerly Cedarview), Clarke, and Greenbank ponds.

5.2 Master Grading Plan

A Master Grading Plan was developed, at a macro-level, for the various parts of the BSUEA lands (refer to Drawings MG1 and MG2 in Appendix M). The design was carried out as follows:

- The proposed centerline road grades displayed within the Mattamy East Lands were derived from the review of the Todd Pond XPSWMM hydraulic model parameters and extracted from the appendix of the Todd Pond Model Keeper Analysis (Re-Assessment of Existing System Capacity) report prepared by J.F. Sabourin and Associates Inc., dated April 2015;

- The New Greenbank Road centerline grades were derived from the July 2014 Environmental Study Report for the Realigned Greenbank Road and Southwest Transitway Extension prepared for the City of Ottawa by the MMM Group;

- The macro-level grading developed for the Brazeau and Drummond Aggregate Extraction Areas was developed based on the greater fill requirement between:

    - the minimum rehabilitation elevation as per Table 3-1: 97.0 m for the Brazeau Aggregate Extraction Area and 104.0 m for the Drummond Aggregate Extraction Area;

    - the minimum 2 m cover requirement over the pits future storm sewer servicing system based on the City of Ottawa's Design Guidelines.

- The macro-level grading within the Minto Lands was developed to target an overall balanced cut/fill site for their overall holdings, rather than on a phase by phase basis. As

previously noted, the topography within the Minto Lands varies significantly throughout the site; several areas have a vertical difference of 5 m within a horizontal length of 80 m. Overall, there is a grade differential of approximately 13 m from west to east (i.e., from 112 m at the north-west boundary to 99 m near Greenbank Road).

Understanding that master grading plans are typically developed at macro-levels as part of MSS documents, the BSUEA Master Grading Plan was prepared with the same concept in mind. Centerline high points, with minimum 0.1% slopes from crests to crests, were established along ROWs and corridors, to identify locations and paths for major overland flow routes. Based on the high points and respective slopes between them, assumptions were made to assess where low points could be accommodated for future roadway sag storage. Overall, a target of 50 m³/ha of storage was anticipated to be achievable, which has been incorporated into the stormwater management strategy that is described in the following sections

5.3 Stormwater Drainage Connections

The storm servicing and stormwater management review undertaken as part of the Existing Condition Report (Section B7.3, Appendix B) found that the BSUEA is not directly connected to any open channel or receiving watercourse. Consequently, runoff from the subject site will have to be collected and conveyed to a downstream receiving watercourse via existing storm sewers, as shown on Figure 5-1, and be controlled at the boundary to meet the residual capacities in the downstream systems. These water quantity measures will ensure that the integrity of the existing storm sewer systems is maintained.

5.3.1 Minto Lands

The topography of the site will allow the Minto Lands (Figure 4-2) to connect into the existing trunk storm sewer system on Greenbank Road, which discharges into the Corrigan Pond. There are also potential connections into the existing Quinn's Pointe Subdivision to the north-east of the Minto Lands (Figure 5-1). These minor system connection points within Quinn's Pointe currently capture drainage from small areas to the west and south under pre-development conditions.

The capacity of the Greenbank Road trunk sewer system discharging to the Corrigan Pond is currently fully utilized as per the design intent of the Quinn's Pointe development, which is located immediately north-east of the BSUEA. The Quinn's Pointe subdivision was approved on the basis of:

i) a Servicing Brief (2014); and

ii) a subsequent Site Servicing Report (August, 2015) both prepared by JLR.

As part of those undertakings, IBI, the model keeper for the Corrigan SWMF and the designer of the Greenbank Road trunk sewer system, was tasked to assess the impact of runoff from the Quinn's Pointe development and southern rural lands both of which is intercepted and conveyed by the Greenbank Road trunk storm sewer to the Corrigan SWMF. IBI's Report entitled "Stormwater Management – Barrhaven South, October, 2014" was appended to JLR's 2014 Servicing Brief (refer to Appendix D for copy of IBI's Report).

The IBI document summarized the proposed stormwater management servicing strategy for the Quinn's Pointe subdivision which consisted on a fixed minor system unit capture rate of 85 L/s/ha combined to a stormwater management facility sited next to Greenbank Road that would intercept major overland flows prior to reaching Greenbank Road. In addition, major overland flow allowances of 0.9 m^3/s and 0.3 m^3/s were allocated to the Quinn's Pointe subdivision via Mattamy's existing subdivision to the north. As part of the model keeper's analyses (Appendix D), the following peak flows were extracted from their model at existing MH102 located at the Kilbirnie and Greenbank Road intersection:

- 1:100 year Qp (3 hour Chicago) = 3.515 m^3/s
- 1:100 year Qp (24 hour SCS) = 3.580 m^3

Detailed storm servicing and grading for Quinn's Pointe was subsequently developed by JLR so that all major overland flows from the subdivision would be conveyed in a southeasterly direction towards a proposed spill-over dry facility where it would be captured and eventually released back into the local storm sewer system, which in turn, discharge into the Greenbank Road trunk storm sewer system and ultimately to the Corrigan SWMF. Consequently, the major overland allowances noted above via the existing Mattamy lands would not be utilized. As part of the Site Servicing Report (JLR, August 2015), the simulated flows at MH102 (Kilbirnie and Greenbank Road intersection) were as follows:

- 1:100 year Qp (3 hour Chicago) = 3.376 m^3/s
- 1:100 year Qp (24 hour SCS) = 3.180 m^3/s

The above flow rates were found to be below those reported by the model keeper, which are inclusive of the Greenbank Road ROW as well as the rural lands on either side of Greenbank Road.

Since a SWMF servicing the BSUEA is proposed west of Greenbank Road and immediately south of Quinn's Pointe, the intent, from a storm servicing perspective, and as shown on Figure 5-1, is as follows:

- Decommission and remove the existing spill-over dry pond that is currently located within the BSUEA lands. As a result, flows in excess of the capacity of the Quinn's Pointe storm sewer system would, therefore, cascade further downstream to the proposed SWMF (northern); and,
- Connect the outlet of the proposed northern SWMF to the Quinn's Pointe 1800 mm diameter trunk storm sewer and install an orifice plate or ICD on the downstream end of the trunk storm sewer upstream of the connection with the Greenbank Road trunk storm sewer in order to control flows.

The above-noted retrofit would allow the proposed SWMFs to fully utilize the dedicated capacity of the Greenbank Road trunk storm sewer. Based on IBI's design of the Greenbank Road trunk storm sewer and subsequent analysis following the 2014 Quinn's Pointe Servicing Brief, peak flows of 3,580 L/s during

PLOT DATE: September 12, 2017 9:08:54 AM

the 1:100 year 24 hour SCS event are allocated to existing MH102, located at the Greenbank Road and Kilbirnie Drive intersection. The design flow in MH102 includes flows from the undeveloped area east of Greenbank Road, Greenbank Road runoff, Quinn's Pointe and any future runoff from the BSUEA.

It should be noted that the above retrofits were envisioned during the detailed design of the Quinn's Pointe Subdivision. As such, residential blocks in the BSUEA that face onto roads in the Quinn's Pointe development have already been accounted for in the Quinn's Pointe modelling. Consequently, no further allowance for these lots is required.

All major overland flow generated by the Minto Lands will have to be captured and detained on-site, as major overland flow cannot be conveyed across Greenbank Road, which is classified as an arterial road. Likewise, there is no allowance in the Quinn's Pointe subdivision for major overland flow from adjoining lands.

In regard to water quality control, the Corrigan Pond was designed as the dedicated end-of-pipe facilities for the Quinn's Pointe Development. As part of the Site Servicing Report (2015) completed by JLR for the Quinn's Pointe Subdivision, an assessment of the water quality volumes was carried out by IBI to confirm that the Corrigan SWMF had the ability to service the subject lands while meeting the enhanced protection level (refer to Appendix D for copy of the assessment). Based on Table 2 of the assessment by IBI, the overall water quality requirements at the Corrigan SWMF were increased to 14,307 m^3 and 5,900 m^3 for permanent pool and extended storage, respectively as a result of adding the Quinn's Pointe Subdivision. The IBI assessment reported that the Corrigan SWMF provided 16,000 m^3 and 6,000 m^3 of permanent pool and extended storage, respectively thereby satisfying the enhanced level of protection. Consequently, the Corrigan SWMF was found to be adequately sized for water quality control for the Quinn's Pointe subdivision.

As a result, no quality control is required for Quinn's Pointe. However, the Corrigan Pond was not sized to provide quality control for the BSUEA lands. Consequently, minor system flows from the Minto Lands will need to comply with the Jock River Reach One Subwatershed Study (Stantec, 2007), which identified a water quality control target of 80% TSS removal. As a result, runoff from the Minto Lands (excluding Quinn's Pointe) will need to meet an enhanced protection level prior to discharge into the Greenbank Road trunk storm sewer.

As depicted on Figure 3-1, part of the Minto Lands currently drains to the Mud Creek subwatershed and Rideau River subwatershed via the Thomas Baxter and Hawley/Hawkins Municipal Drains, respectively. Any additional runoff conveyed to these Municipal Drains would need to be documented in an Engineers Report in accordance to the Drainage Act.

5.3.2 Mattamy Lands East

The Mattamy Lands East are located next to the existing Mattamy Half Moon Bay South subdivision that is fully serviced by a storm sewer system (Figure 4-2), and is part of the Todd Pond serviced area. The system was sized for the Half Moon

Bay South subdivision, and includes capacity to convey rural drainage from the Mattamy Lands East within the BSUEA. The Mattamy Lands East can, therefore, utilize this dedicated capacity in the minor storm system of the adjoining Half Moon Bay South development. The stormwater management servicing of the Half Moon Bay South development has been approved by the City of Ottawa as per the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, August 2017). The modelling carried out for the Phase 4 Stormwater Management Report included the Mattamy Lands East as fully developed under their ultimate servicing solution scenario. Extracts of the Stantec report are contained in Appendix H of this Report.

5.3.3 Mattamy Lands West

The Mattamy Lands West lands are located south of the proposed Half Moon Bay West development and west of New Greenbank Road (Figure 4-2). The lands are tributary to the proposed Clarke Pond, as identified in the Draft 2014 BSMSSA (Stantec). The Mattamy Lands West area was accounted for in the following two (2) studies:

1. The hydrological analysis of the Draft 2014 BSMSSA showed these lands as an urbanized area where post-development flow was captured by the New Greenbank Road trunk sewer, and

2. The conceptual modeling of the Clarke Pond, undertaken by JFSA (Design Brief for the Clarke Stormwater Management Pond for the Half Moon Bay West Subdivision, August 2017), included an undeveloped portion of the Mattamy Lands West area and potential connections to the Clarke Pond from this area.

The Mattamy Lands West area is part of Catchment Area A227C of the Draft 2014 BSMSSA, which includes an area of 4.75 ha at a total imperviousness of 71.4 %. The Draft 2014 BSMSSA has identified and accounted for a 1:5 year capture for this catchment. However, the Study also states that the catchment will be required to incorporate on-site storage such that full retention of the 1:100 year major overland flow should be provided to prevent flows from spilling onto New Greenbank Road. On-site storage can be provided by a spill-over dry pond unless servicing of the Mattamy Lands West can incorporate sufficient on-site storage such as rooftop, road sag and/or underground storage.

The design sheets prepared as part of the Draft 2014 BSMSSA include a lumped area assigned to the node at the point of Mattamy Lands West. However, by extracting catchment A227C from the design sheet, the allowable release rate assigned to these lands and directed to the trunk storm sewer is 880 L/s. Based on the HGL analysis completed by Stantec as part of the Draft 2014 BSMSSA, it was reported that the sewer at this location does not operate under surcharged conditions during the 1:100 year event. On this basis, minor system capture from this site should be limited to 880 L/s and servicing should also incorporate measures to detain the major overland flow.

5.3.4 Brazeau and Drummond Aggregate Extraction Areas

A significant portion of the Brazeau and Drummond lands are currently operated as aggregate extraction areas. The active portion of those lands has lower elevations than the surrounding topography. The Existing Condition Report (Appendix B) identified that prior to operating as aggregate extraction areas, these lands naturally drained north, either via north-east or north-west overland flow paths. As a result, it is envisioned that any post development flow from these future rehabilitated areas would have to:

- Meet the existing flow in the downstream system;
- Meet the quality control target of 80% TSS removal as per the Jock River Reach One Subwatershed Study (Stantec, 2007); and,
- Preserve pre-infiltration condition levels

In order to provide positive drainage to a storm outlet, both properties will need to be rehabilitated to the minimum elevations (Table 3-1) specified by the Ontario Ministry of Natural Resources.

As identified in the Existing Conditions Report (Appendix B), the culvert downstream of the aggregate properties receives a pre-development flow of 1,300 L/s during the 1:100 year event. During detailed design, servicing of both properties should be developed such that the downstream pre-development flow is not exceeded. Any downstream system should have sufficient capacity for the pre-development flow.

5.4 Site Storm Drainage Criteria

The functional design of the storm sewer system was developed for the BSUEA in accordance with the OSDG and Technical Bulletin PIEDTB-2016 while the sizing of the SWMFs has been based on the Ontario Ministry of Environment (MOE) Stormwater Management Planning and Design Manual (SWMPDM) 2003. Specifics and design criteria for both minor and major systems is described below.

5.4.1 Minor System

The storm sewers servicing the BSUEA are to be designed in accordance with the OSDG and associated Technical Bulletins as summarized below:

<u>Design Capture and Level of Service</u>

- Minimum 1:2 year and 1:5 year capture for local and collector roads, respectively
- 1:10 year capture for arterial roads, Transitway or any depressed driveways

<u>Design Flows</u>

- Initial sizing of the storm sewer via the Rational Method design sheets with final sizing to be confirmed via an HGL analysis

- IDF Rainfall statistics as per OSDG
- Time of concentration (Tc) based on an inlet time of 10 minutes
- Runoff coefficients to be based on recently approved developments of similar nature as per Section 5.4.5.2.2 of the OSDG

Design Criteria

Design Criteria as per the OSDG

- Minimum velocity 0.80 m/s
- Maximum velocity 6.0 m/s
- Manning roughness coefficient 0.013
- Minimum allowable slopes See Table 6.1 of the OSDG
- Minimum depth of cover 2.0 m
- Minor losses at manholes set in accordance with Appendix 6B of the OSDG
- Inlet control rate to be achieved with inlet control devices (ICDs) with minimum capture of 1:2 year for locals, 1:5 year for collectors and 1:10 year for arterials

5.4.2 Major System

The storm servicing for the BSUEA was developed following the dual drainage concept: the minor system is sized based on the criteria set out in Section 5.4.1, while the major system is configured based on the criteria outlined below and evaluated in accordance with the OSDG and Technical Bulletins.

Maximum Flow Velocity on Streets

The product of velocity (m/s) and depth (m) of overland flow on streets shall not exceed 0.6 for a 1:100 year peak flow.

Major System Flow Outlets

Major system flow should outlet to either a watercourse or a SWMF.

Road types and Allowable Flow Depths

- Local: 350mm at edge of pavement
- Collector: 250mm at edge of pavement
- Urban Arterial: No barrier curb overtopping; arterial should be designed to leave one lane free of water in each direction during the 1:100 year design storm
- In the absence of barrier curbs, flow shall not encroach into adjacent private property

5.4.3 Stormwater Management Facilities (SWMFs)

The SWMFs, either wet ponds or dry ponds, should be designed in accordance with Section 8 of the OSDG and MOE's publication entitled "SWM Planning and Design Manual, 2003".

The normal water level in the wet ponds should be above the highest elevation of either: (i) the free flowing water level in the downstream storm sewer during the 1:2 year event; or (ii) the elevation of the underlying groundwater table.

For safety reasons, the live storage in dry ponds should be kept to 1.5 m (OSDG) to 2.0 m deep (MOE). A minimum 300 mm freeboard should be provided between the 1:100 year water surface elevation and the overflow elevation.

SWMFs should be integrated into the community through the use of pathways or other linkages.

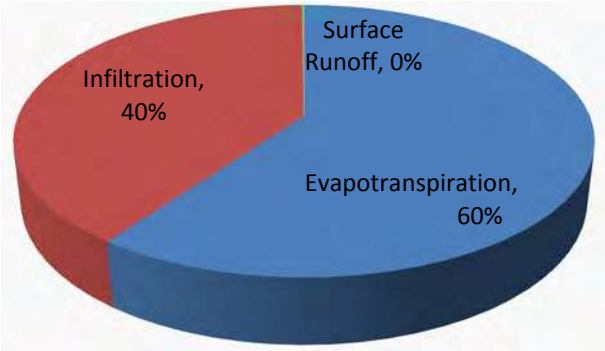
5.4.4 Water Balance

The Hydrogeological Existing Conditions Report (Paterson Group Inc., 2017) recommended that infiltration measures be incorporated into the BSUEA's storm servicing design, as the subject area contributes to groundwater recharge of the esker, which should be preserved. The Paterson Group Inc. (Paterson) Report recommended that:

- Distributed infiltration be achieved to promote recharge of overburden aquifer and preserve the pre-infiltration condition for the three (3) subwatersheds; and,
- Only captured runoff that is relatively free of roadway salts be infiltrated to minimize adverse impacts on the esker.

An analysis (using the PCSWMM software platform) was carried out and is summarized in the Existing Condition Report (Appendix B) to determine the various contributions of the water budget based on long-term simulations. To simulate the infiltration, the analysis utilized measured data compiled as part of Paterson's field program. Infiltration to groundwater recharge zones was simulated based on measured saturated field hydraulic conductivity, which was translated to infiltration rates (refer to Section B6.1.1 of Appendix B). The analysis revealed that overall pre-development infiltration from the subject site (excluding the aggregate extraction areas) accounted for 40% of the overall water budget (Figure 5-2). The City and RVCA have agreed with Paterson's recommendation that pre-development infiltration levels should be maintained and distributed infiltration be achieved across the site, and should not be concentrated at one or two location(s).

Figure 5-2: Existing Water Budget Breakdown



5.5 Storm Servicing Strategy

Based on the storm drainage connections and criteria set out in Sections 5.2 and 5.4 respectively, a stormwater management strategy has been developed. The strategy strives to preserve pre-development infiltration across the BSUEA, which in turn, impacts the individual stormwater management strategies developed for each of the servicing areas depicted in Figure 4-2. Sub-section 5.4 presents the rationale in developing storm servicing strategies, Sub-section 5.5.5 the storm drainage and design methodology, Sub-sections 5.7 5.8, and 5.9 present the analyses carried out for the conventional, EES and infiltration gallery servicing strategies, respectively while Sub-section 5.10.2 summarizes the impact of the strategies on the municipal drains.

5.5.1 EES Infiltration Strategy

5.5.1.1 Background

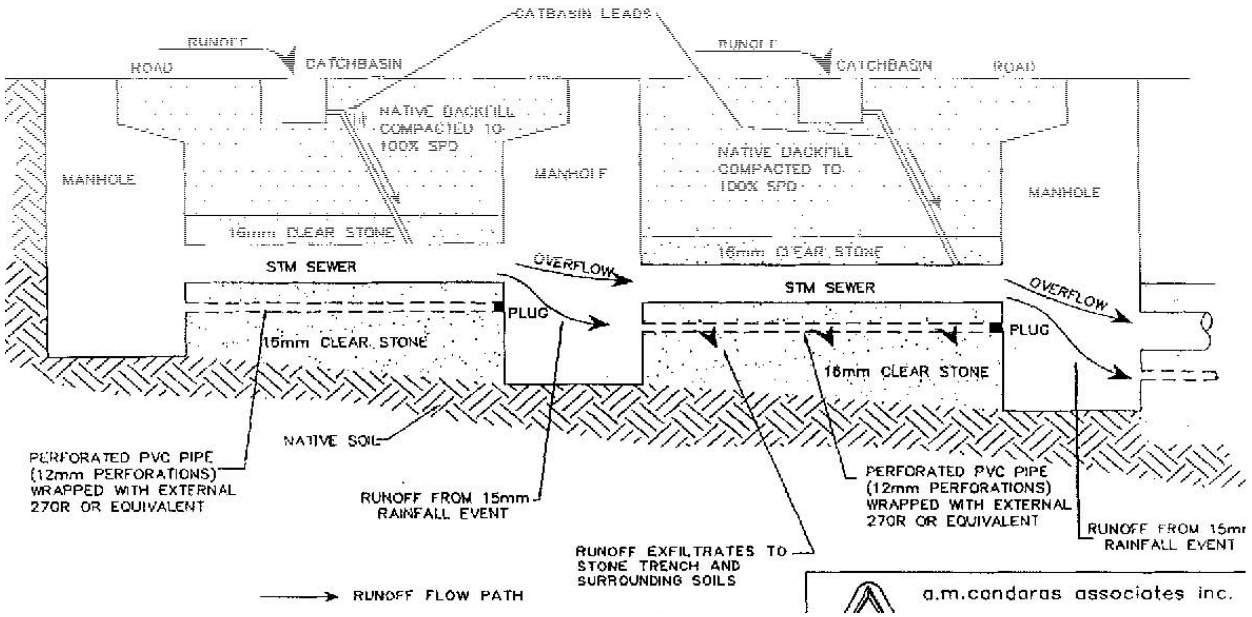
During the preparation of the Existing Condition Report, it became evident that storm servicing for the BSUEA would need to incorporate measures to recharge the overburden aquifer. As a result of extensive work and consultation with the both the City and RVCA over a nine (9) month period, the preferred infiltration servicing strategy has been identified as the Etobicoke Exfiltration System (EES). During this nine (9) month period, a number of Memoranda were prepared to support the selection process. All documents and work undertaken (Memoranda and Presentation) are described below (Sections 5.5.1.1 to 5.5.1.6) and included in Appendix E.

In September 2016, a Memorandum to the City outlined potential infiltration measures that could be considered for the BSUEA. The Memorandum outlined general considerations related to infiltration and nine (9) specific infiltration measures, which ranged from reduced lot grading to infiltration galleries and bio-retention cells. The advice from the City and RVCA following submission of the Memorandum is that infiltration measures should be spread across the site so as to mimic current infiltration patterns and should not rely on infrastructure on private properties. After further review and discussions, the EES was selected as the preferred measure to preserve the water budget and carried forward for further sizing and analysis.

The main benefit of implementation of the EES is that it is contained within the ROW and not subject to maintenance by individual property owners who are difficult to hold responsible and the nature of the distributed infiltration will preserve groundwater drainage boundaries.

The EES (Figure 5-3) was developed, designed and constructed in the former City of Etobicoke (now part of the City of Toronto) in 1993. Its main objective was to restore the natural hydrologic cycle in an existing developed area. The EES consists of two perforated pipe sub drains constructed below the conventional storm sewer that is surrounded by a clear stone media, which collects and detains surplus stormwater runoff before reaching the conventional storm sewer line. The downstream ends of the perforated pipes are capped. The EES is intended to capture frequent storm events and the initial "first flush" of large storm events by trapping flow in the perforated pipe sub drain and surrounding media. It is also intended to infiltrate runoff from frequent events into the surrounding soils, while runoff from larger events will overtop the capacity of the EES system and would then overflow to the conventional storm sewer system above.

Figure 5-3: Diagram of Typical EES Application



5.5.1.2 Sizing of EES

To investigate the sizing and performance of the EES, a test simulation was developed using the PCSWMM software platform. The test simulation consisted of an urbanized area of 2.7 ha that reflected the anticipated type of development within the BSUEA. The test simulation used infiltration parameters calculated from Patersons' measured saturated field hydraulic conductivities, which were reduced by a factor of safety of 2.5 as per the guidance from Credit Valley and Toronto and Region Conservation Authorities on Low Impact Development. It was determined that PCSWMM could be utilized to simulate the EES, and the results of the test simulation indicated that the system was sized in accordance with the document

entitled “Planning and Design Manual of the Etobicoke Exfiltration System” met and exceeded the pre-infiltration rates when applied across the overall BSUEA.

According to the “Planning and Design Manual of the Etobicoke Exfiltration System”, the EES should detain and infiltrate up to the 95th percentile rainfall event. An analysis of the 30 year long-term rainfall used for the continuous simulation shows that the 95th percentile is approximately 22 mm of rainfall; hence, a 22 mm capture was used as the sizing criteria.

5.5.1.3 EES versus Water Quality Control

Storage volume requirements to achieve an 80% TSS removal using infiltration measures are summarized in Table 3.2 of the MOE “Stormwater Management Planning and Design Manual, March 2003”. Based on the average imperviousness used in the test model, the required volume of water quality storage for the EES to achieve 80% TSS removal is 32 m³/ha. Based on an EES sized for the 95th percentile storm, the storage volume in the test model is on average 150 m³/ha. The proposed EES system, therefore, satisfies the requirements for water quality control in accordance with the MOE for any of the proposed land uses and means that further downstream water quality controls would not be required for areas serviced with the EES.

5.5.1.4 Presentation of Potential Infiltration Measures

On May 24, 2017, a presentation was made to the City focusing on two (2) potential infiltration measures that could be implemented in the BSUEA to maintain the pre-infiltration levels. The measures presented included the EES (discussed above) and an additional infiltration measure that was implemented in Vaughan: the Clean Water Collector (CWC). Subsequent to this presentation, the City advised that the EES was more suitable than the CWC since the infrastructure is solely located along municipal ROWs. A copy of this presentation is included as an appendix to the Memorandum discussed below in Section 5.5.1.6.

5.5.1.5 Impact of Salting Practice on the EES

Following presentations to City staff and a request from the City in June 2016, a further Memorandum was provided outlining the application of the EES across site, but only on local roads and their respective catchments. The intent is to prohibit any infiltration of roadway runoff to occur when originating from either collectors or arterials due to the salting practices adopted for those roadways. The spreadsheet calculations on applying the EES in limited areas found that infiltration rates pre- and post-development would remain similar. The implementation of an EES along roadways impacted by salt applications would capture runoff with chlorides, which could adversely impact the quality of the overburden aquifer during periods of melt.

5.5.1.6 Operation and Maintenance Memorandum

At the request of the City, a Memorandum was prepared outlining recommended operation and maintenance practices that would be anticipated should the City accept the EES infrastructure. This Memorandum issued on June 22, 2017

indicated that maintenance associated with an EES would marginally increase when compared to conventional systems as there would be a need to flush the two (2) perforated sub drains. Based on the information gathered by the TRCA in 2013, flushing of the EES in the former City of Etobicoke was completed approximately twenty (20) years following the last cleanout of the system. Once flushing was completed, it was determined via testing that the original infiltration capability of the system was reinstated. On that basis, assuming and adopting a twenty (20) year flushing frequency would be consistent with the current practice within the City for conventional storm sewer system.

5.5.1.7 Assessment of EES in the BSUEA

Given that the operation and maintenance requirements associated with the EES exceeds that of a conventional storm sewer system, there is an uncertainty whether the adopted storm servicing strategy will incorporate an EES. As a result, this MSS was prepared considering; i) a conventional storm sewer system incorporating an EES along local roads, and ii) the standard conventional system.

To allow flexibility, this MSS has reviewed the servicing needs of the BSUEA for the EES servicing solution as well as a conventional system. Based on this review, the Minto Lands are those with the greatest difference in servicing needs of the BSUEA. As an example, servicing of the Minto Lands with a conventional storm sewer system will result in the need for wet ponds to achieve the MOE protection level. Conversely, should an EES be incorporated within the servicing of the Minto Lands, the end-of-pipe facilities at Greenbank Road will consist of dry ponds due to the water quality treatment level inherent in the EES that exceeds, by far, the minimum MOE requirement. Other areas such as the Mattamy Lands East and Mattamy Land West would not be impacted by the alternative servicing options as they are both tributary to an existing storm sewer system that discharge to the Todd Pond and there would not be any subsequent changes in storm sewer sizing.

The stormwater management strategies developed for each of the areas depicted on Figure 4-2 is presented below for each strategy namely the conventional system or the EES. Consequently, Section 5.5.3 presents the conventional servicing strategy and associated results summarized in Section 5.7 while Section 5.5.4 and Section 5.8 provides an overview and simulation results respectively of the EES strategy as outlined in this section of the report.

5.5.1.8 Monitoring Requirements in the BSUEA

During the course of the Existing Condition Report, the City of Ottawa acknowledged that they own and operate a few systems within their jurisdiction that rely on exfiltration without detail knowledge on either their performance or maintenance requirements. Although the EES has been used in the City of Ottawa and elsewhere in Ontario, it is proposed that monitoring of the system be undertaken to assess and confirm that it operates as proposed. The details and extent of flow monitoring should be discussed and reviewed by the City as part of Draft Plan and confirmed at the detailed design stage of the initial phase of both builders (Minto and Mattamy). The intent of the EES monitoring is two-fold; to estimate the drawdown time of the EES (i.e., time for water levels in the system to

drop) and also to determine an average rate of capture before runoff is conveyed by the traditional sewer system.

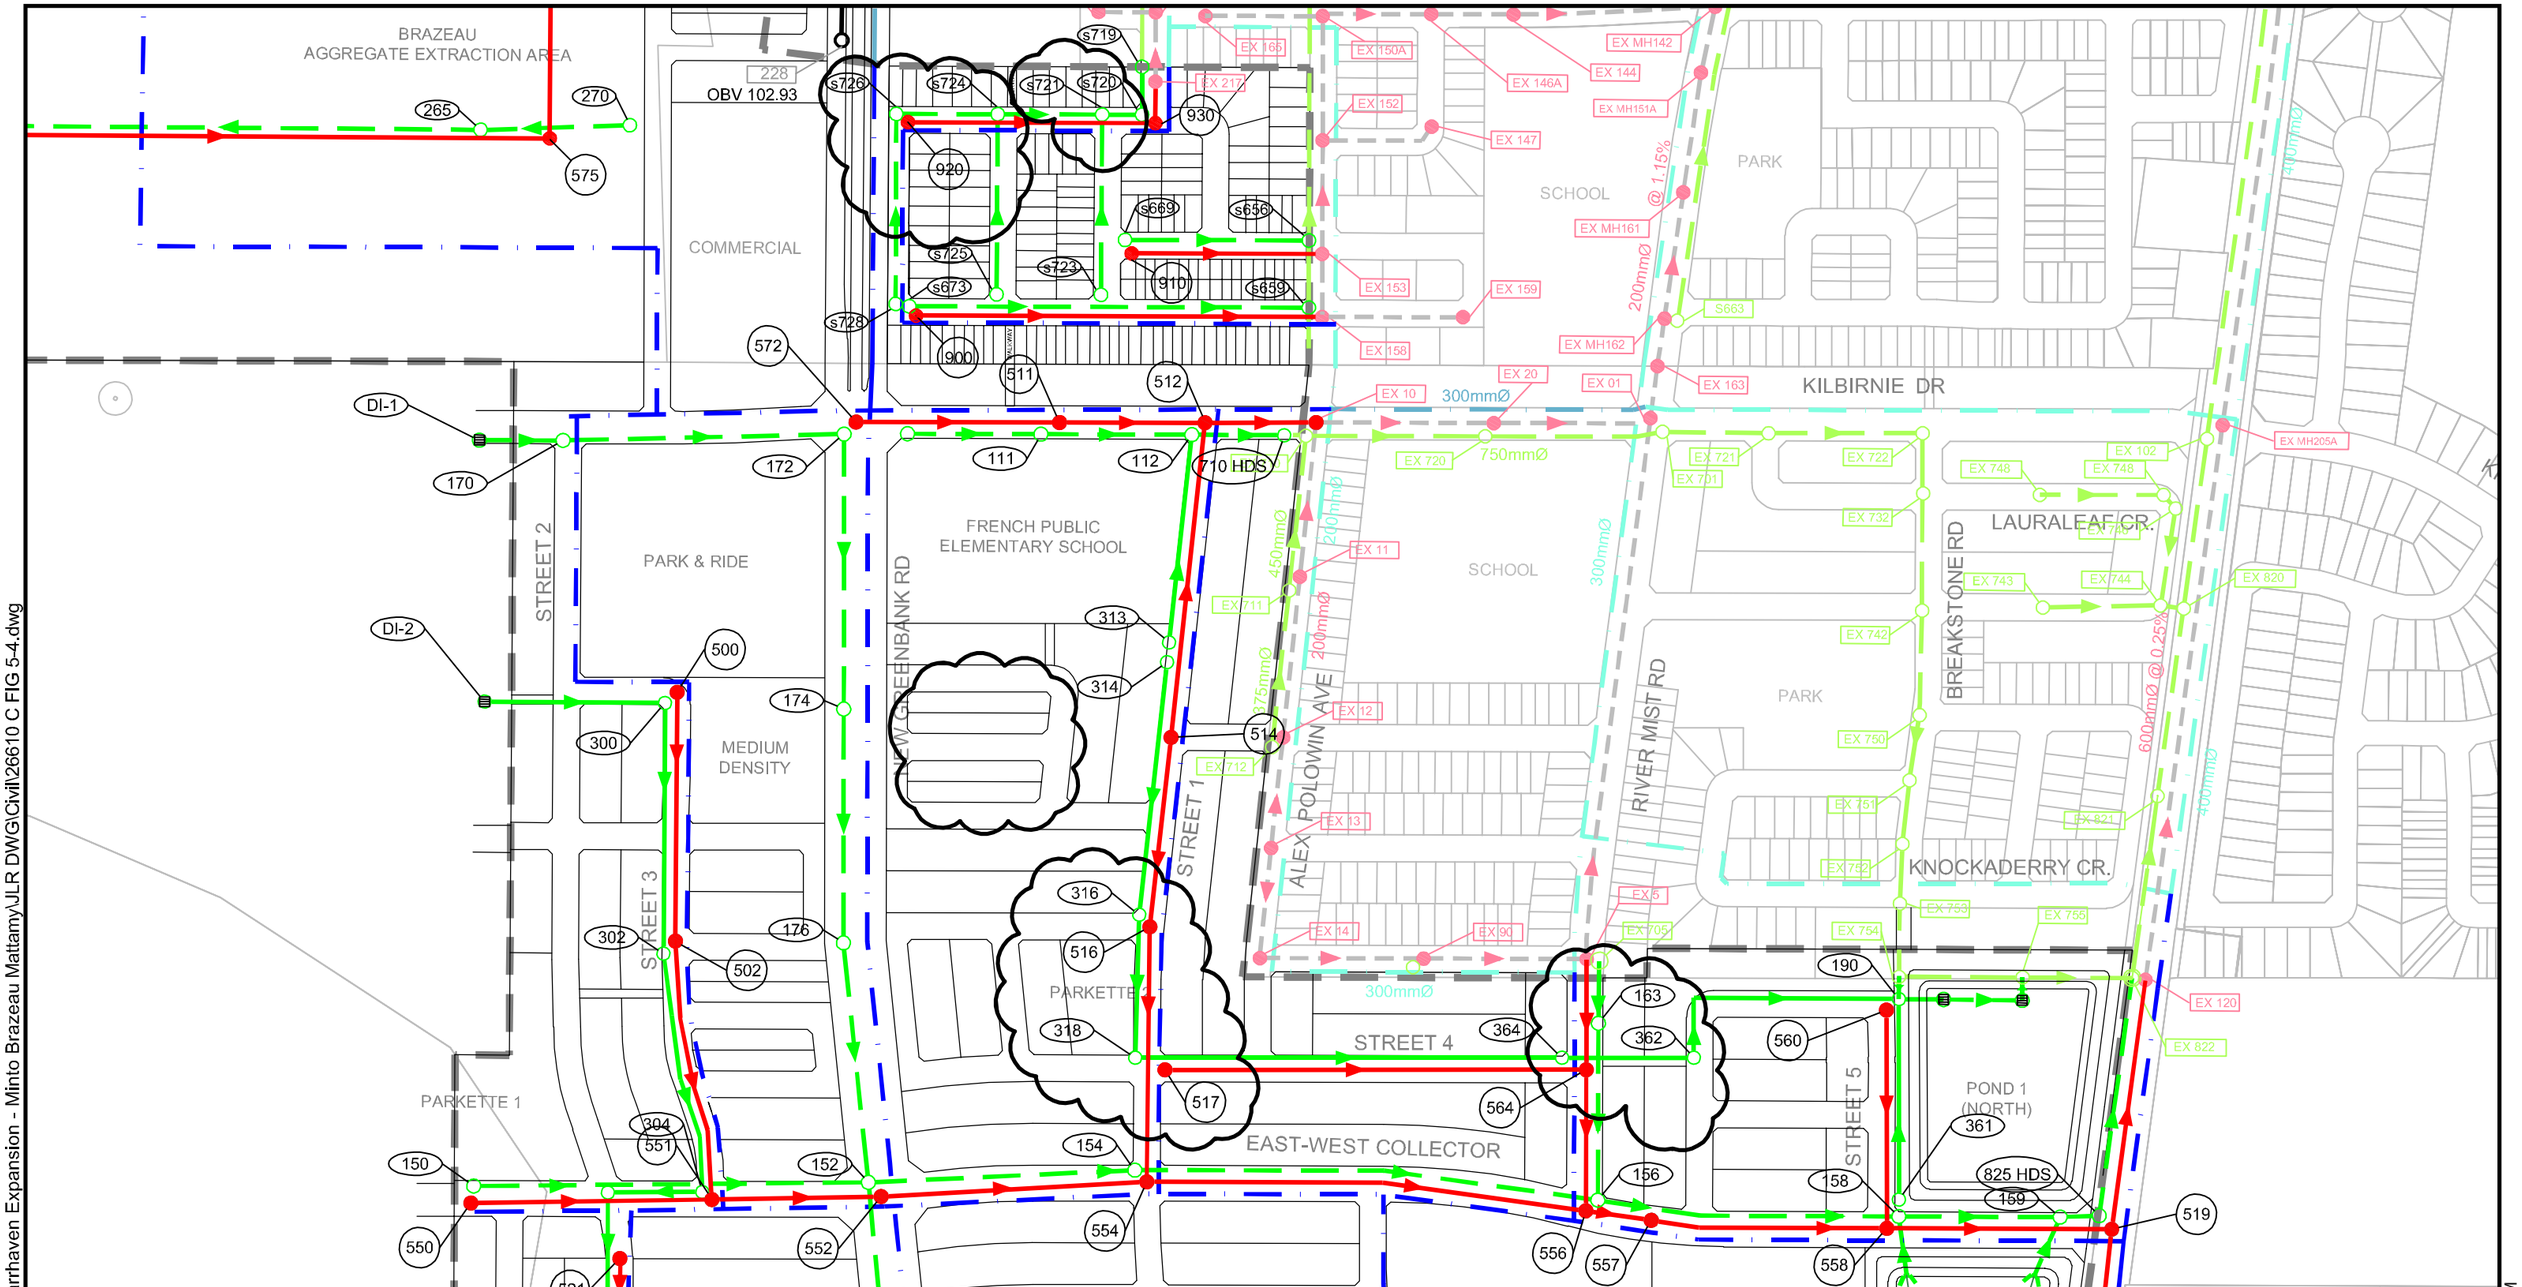
It is proposed that monitoring locations be set, in general, within the areas depicted on Figure 5-4. Based on discussions held with the City, the EES should be monitored at five (5) locations; three (3) locations within the Minto Lands (Phase 1) and two (2) within the Mattamy Lands (Phase 1). The exact location within each of the five (5) areas should be discussed with the City. Given that the existing Quinn's Pointe Subdivision does not include an EES, the most downstream flow monitoring location within the Minto Lands should be set upstream of Manhole No. 190, preferably near Manhole No. 362/364. Due to the variability of soils (hydraulic conductivities), it is proposed that the initial phase of both builders (Minto and Mattamy) include one location near the upper end of their EES and one near the downstream end of the system. In regard to Minto's third flow monitoring location, it is recommended that it be set mid-way of their Phase 1 lands. Flow monitoring should be set up to capture runoff from the spring freshet when the groundwater levels are likely to be near their maximum and span for a period of around 6 months. In order that an assessment of the EES can be made prior to development of subsequent phases of the CDP area, it is recommended that monitoring be initiated when 50% or more of the Phase 1 area serviced by the EES is developed and occupied.

Other monitoring requirements are further described in Paterson's latest Existing Conditions Report and Morrison Hershfield's Environmental Management Plan (EMP). The following monitoring is also to be completed:

- Baseline monitoring of existing drinking water wells in accordance with Paterson's recommendations described in Section 5 of their ECR; and
- Baseline monitoring of chloride and bromide under pre-development conditions to set the baseline condition as well as future monitoring which will necessitate the construction of monitoring wells in the overburden at strategic locations. Similar to the EES monitoring, five (5) monitoring wells should be constructed; three (3) within the Minto Lands and two (2) with the Mattamy Lands. The location of these monitoring wells are to be discussed at Draft Plan stage. Additional details have been provided in Section 4.3.6 of the EMP.

5.5.2 Infiltration Gallery Strategy

Section 5.5.1 provided a summary of the process followed throughout the course of the Existing Conditions Report and Master Servicing Study with respect to the selection of the EES servicing strategy as a means to promote infiltration. To support the EES, flow monitoring is proposed as part of initial phase of development (refer to recommendations made in Section 5.5.1.8). Should flow monitoring not show the effectiveness or maintenance of the EES proves to be more exhaustive than what was assumed then an infiltration gallery is an alternate servicing strategy which is investigated at a high level to replace the EES.



POTENTIAL LOCATION FOR EES MONITORING

NOTE:

- BASELINE MONITORING OF EXISTING DRINKING WELLS TO BE PERFORMED IN ACCORDANCE WITH PATERSON'S EXISTING CONDITIONS REPORT.
- BASELINE MONITORING OF CHLORIDE AND BROMIDE TO BE COMPLETED UNDER PRE-DEVELOPMENT AND POST-DEVELOPMENT CONDITIONS AT FIVE (5) LOCATIONS (MINTO (3) AND MATTAMY (2)) IN ACCORDANCE WITH THE ENVIRONMENTAL MANAGEMENT PLAN.

FIGURE 5-4

PLOT DATE: May 3, 2018 1:27:14 PM

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\Civil\26610 C FIG 5-4.dwg

The infiltration gallery investigated conceptually consists of an underground system made of proprietary manufactured modular structures surrounded by a clear stone envelope, which provides storage in its voids. The overall system creates temporary storage for runoff, which in turn, would exfiltrate/infiltrate into the underlying native soil in areas that are conducive to infiltration.

5.5.2.1 Sizing Basis

The infiltration gallery should, similarly to the EES, be sized to capture the 22mm rainfall event, which was found to approximately represent the 95th percentile rainfall. By adopting this sizing criterion, the aim is for the area serviced by this system to preserve pre-infiltration levels. The hydraulic conductivity of the soils underlying the gallery would be sourced, as per the EES design, from the Paterson's measured saturated field hydraulic conductivities, which would then be transformed into an infiltration rate as per the methodology described in the Ontario Ministry of Municipal Affairs and Housing (MMAH) Building Code Supplementary Standard SB-6 (2012).

Since the gallery would be sized to capture the 22 mm event, it is envisaged that the storage volume would be similar to the 150 m³/ha stored in the EES. Consequently, the storage capacity of 150 m³/ha provided by such facility would be greater than the 32 m³/ha required to achieve 80% TSS removal under the MOECC SWMPDM. As a result, no further water quality treatment storage would be required for the area serviced by an infiltration gallery. The 150 m³/ha estimate should, however, be confirmed during the design stage.

5.5.2.2 Location and Serviced Area

The infiltration gallery would be best suited where soils were reported as having high hydraulic conductivities. The higher the soil capacity for infiltration, the more efficient the size of the infiltration gallery will be. It is recommended that the gallery not be placed under private property or within ROW corridors. The infiltration gallery must also be in a location with easy access for operation and maintenance.

Similar to the EES, the area serviced by an infiltration gallery should be free of road salts in order to prevent adverse impact on the underlying groundwater. Consequently, the area serviced by an infiltration gallery should only consist of local roads and residential lots.

5.5.2.3 Operation and Maintenance

The performance of infiltration galleries is often found to be impacted by sediment deposition, which seals the bottom and hinders the ability of soils to allow infiltration. As a result, pre-treatment is often incorporated in the design of infiltration galleries to minimize accumulation of sediments. Should an infiltration gallery be proven to be required, it is recommended that it be combined with a HDS sized to provide pre-treatment similar to a sedimentation forebay in a wet pond. The HDS should be sized to achieve a minimum of 60% TSS removal.

The infiltration gallery and pre-treatment device will require regular maintenance which will include annual as well as long term activities. Maintenance would be twofold; maintenance of the pre-treatment device (i.e., HDS) and maintenance of the infiltration gallery. The former would be consistent with the manufacturer's recommendations which is typically every year while the latter would consists of more frequent tasks; cleaning out leaves, debris and accumulated sediment caught in inlets and outlets annually or as needed. Inspection via a monitoring well should be performed on an annual basis to ensure the facility drains within 72 hours following a major storm event (>25 mm). If the time required to fully drain exceeds 72 hours, then the gallery should be drained via pumping and cleaned out. If the slow drawdown time persists then the system may need removal and replacement of granular material and/or geotextile fabric.

5.5.2.4 Assessment of Infiltration Galleries in the BSUEA

There is some uncertainty at this time as to confirm whether storm servicing of the BSUEA will incorporate measures to promote infiltration such as an infiltration gallery or an EES. This uncertainty mainly lies with the increased maintenance requirements such a system would potentially impose on the City. The implementation of an infiltration gallery with pre-treatment will be assessed at a very high level in this MSS to determine the effectiveness of such a system.

5.5.3 Conventional System

5.5.3.1 Minto Lands

The only potential and feasible downstream minor system connection for the Minto Lands is the existing connection along the Greenbank Road trunk storm sewer system, which conveys captured flows to the Corrigan Pond. Due to falling topography from west to east, there are no major system outlets available to the Minto Lands as the Greenbank Road forms a barrier. In order to maximize the minor system connection at Greenbank Road, all major and minor system flows will have to be captured and controlled to the dedicated capacity in the Greenbank Road storm sewer. Flows from the adjoining Quinn's Pointe development will also have to be controlled by the stormwater management facilities to be located within the Minto Lands.

The preferred Demonstration Plan (Section 4.3 and Figure 4-2) identified three (3) stormwater management blocks for the purposes of providing quantity and quality runoff control for the Minto Lands. The facilities include two (2) stormwater management blocks on the eastern side of the BSUEA next to the connection to the Greenbank Road storm sewer and a single spill-over dry pond on the western edge of the BSUEA. The minor system for the Minto Lands will drain to the stormwater management blocks and the major overland flow will be divided between the end-of-pipe facilities to the east and the spill-over dry pond to the west.

The major system overland flow routes within the BSUEA are defined from the preliminary grading plan developed for the site. The Master Grading Plan has been developed to convey overland flow to the respective collection points as shown on

Drawing MG1. Overland flow is not permitted to cross arterial roads, such as New Greenbank Road, which runs through the site north to south. Overland flow is, therefore, directed away from the arterial ROW and towards the SWMFs.

Major overland flow from the areas west of New Greenbank Road will be conveyed towards the spill over dry pond located just outside of the western boundary of the CDP, along Barnsdale Road. Major overland flow from the areas east of New Greenbank Road and south of the new East-West Collector Road will be conveyed towards the SWMF located at the intersection of Barnsdale Road and Greenbank Road. The majority of the area east of New Greenbank Road and north of the East-West Collector Road will drain towards the SWMF at Greenbank Road. However, parts at the northern end will drain towards the adjoining Quinn's Pointe development. Capture rates in this area will have to be increased as there is insufficient street ponding storage to capture and detain runoff without cascading into Quinn's Pointe with just a 1:5 year capture rate. Based on past analyses, no flow can cascade into Quinn's Pointe as the area has no capacity in the major system.

Under the conventional storm system, there would be a requirement for wet ponds to provide water quality treatment and fulfil the enhanced protection level.

A conventional sewer system will result in a reduction of the infiltration levels due to the hard surfaces and the lack of measures to promote infiltration. Hence, the pre-development infiltration level would not be preserved. In terms of the operation and maintenance requirements, this servicing option would be the same to any other conventional systems with two wet ponds.

5.5.3.2 Mattamy Lands East

The Mattamy Lands East can connect to the existing minor system in the Half Moon Bay South development. The Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015) has assessed the impact of servicing the Mattamy Lands East through the Half Moon Bay South development and into Todd Pond. As stated in the 2015 Stantec report, the inclusion of the 5.6ha Mattamy Lands East lands to the Todd Pond drainage boundary via the Half Moon Bay South subdivision has been confirmed by the JFSA Todd Pond Model Keeper analysis and approved by City staff.

5.5.3.3 Mattamy Lands West

As identified in the Draft 2014 BSMSSA (Stantec), the dedicated storm outlet for the Mattamy Lands West is the proposed New Greenbank Road storm sewer system that would flow northerly and outlet to the Clarke Pond. A release rate of 880 L/s was accounted for in this storm sewer system as per the Barrhaven South MSS design sheet. Flows in excess of 880 L/s up to the 1:100 year event must be detained on-site by means of street sag storage or a dry pond, or a combination of both. In the case that detailed design shows that street sag storage is sufficient to detain the 1:100 year major overland flow then a dry pond may not be warranted.

5.5.3.4 Brazeau and Drummond Aggregate Extraction Areas

The redevelopment of the Drummond and Brazeau Aggregate Extraction Areas will occur in the future once the rehabilitation grades are achieved. In addition, the preparation of Existing Conditions Reports for both aggregate pit areas will need to be completed prior to their development. At such time, it is proposed that post-development surface flows follow pre-development flow path to the north-west of the site. In order to fulfil the criteria listed in Section 5.3.4, quantity and quality control will have to be provided prior to discharge, either via on-site controls or a SWMF depending on final land use configuration. It is envisioned that both aggregate extraction areas will need to preserve pre-infiltration levels. As a result, storm servicing for both areas will need to incorporate measures that would promote infiltration.

The potential storm servicing strategy for the aggregate extraction areas is based on the phasing of each aggregate extraction area. The land owners have indicated that development will not proceed in tandem and each property will require their own stormwater management solutions with two (2) separate SWMFs and two (2) separate outlets. The outlets will discharge to a trunk storm sewer along Borrisokane Road which will convey flows to the Jock River.

5.5.4 EES Infiltration Approach

5.5.4.1 Minto Lands

The implementation of infiltration type measures within the Minto Lands would involve the EES infrastructure (i.e., sewers and granular envelope), as described in Section 5.5.1, combined with conventional conveyance sewers located above. The overall stormwater strategy would remain as per the conventional system outlined in Section 5.5.3.1; there would be two (2) downstream end-of-pipe facilities in the south east of the BSUEA and a dry spill-over pond to the west. The underground storm infrastructure would incorporate the EES and the stormwater management facilities would not require any water quality component. As a result, the facilities would be dry ponds.

Due to the salting practice within the City, it is proposed to incorporate an EES within areas such as local roads and associated residential runoff so that the captured runoff is relatively free of roadway salts due to the implications outlined in Section 5.5.1.5. The current salting practice showed that salt is not applied on local roads on a regular basis. However, it is applied on the collector and arterial roads.

Where residential units are fronting collector roads, storm servicing would be carried out solely with a conventional storm sewer system. However, in order to maximize infiltration via an EES, all rear-yards should be directed to an EES network where possible. In addition, it is recommended that servicing of the park and ride block, commercial block and school blocks exclude an EES due to the potential salt application within these land usages. Given that significant portions of commercial and institutional blocks include rooftops of up to 30% coverage, the modelling was carried out assuming that rooftop flows should continue to be

captured and infiltrated up to the 95th percentile storm (a 22 mm event, Section 5.5.1.2). Runoff in excess of 22 mm would either be directed to a local road EES (if feasible and practical) or be discharged into the collector conventional system.

Since the EES sewers will provide water quality treatment to 80% TSS removal or enhanced protection (Section 5.5.1.2), no further downstream water quality treatment of EES sewers will be necessary. Consequently, runoff in excess of the capacity of the EES can be conveyed to the end-of-pipe facilities that would consist of dry ponds for water quantity control prior to release into the Greenbank Road trunk storm sewer.

Conversely, water quality control would still be required for the areas draining to the conventional sewer system, including the arterial and collector roads as well as the land use areas with salt applications. Due to the smaller extent of these areas and the lack of flow during frequent storm events, the proposed servicing strategy includes the provision of a Hydro Dynamic Separator (HDS) at the downstream end of the conventional system immediately near the dry ponds. The servicing strategy that includes an HDS was selected over having wet detentions ponds, as the latter could experience problems such as an algae bloom or West Nile Virus; in frequent events the majority of the runoff will be captured by the EES and there will be a lack of flow to any downstream treatment facility.

Overall, the size of the end-of-pipe facilities would be reduced as the exfiltration of the EES will reduce the overall volume of runoff conveyed to the ponds, which in turn, will result in lesser storage volume requirement.

Major overland flow from the areas west of New Greenbank Road will be conveyed towards the spill over dry pond located just outside of the western boundary of the CDP, along Barnsdale Road. Major overland flow from the areas east of New Greenbank Road and south of the new East-West Collector Road will be conveyed towards the SWMF located at the intersection of Barnsdale Road and Greenbank Road. The majority of the area east of New Greenbank Road and north of the East-West Collector Road will drain towards the SWMF at Greenbank Road. However, parts at the northern end will drain towards the adjoining Quinn's Pointe development. Capture rates in this area will have to be increased as there is insufficient street ponding storage to capture and detain runoff without cascading into Quinn's Pointe with just a 1:5 year capture rate. Based on past analyses, no major overland flow can cascade into Quinn's Pointe as the area has no capacity depth wise along the major system.

5.5.4.2 Mattamy Lands East and Mattamy Lands West

The stormwater management strategy for the lands part of the Mattamy Lands East and Mattamy Lands West would not vary from that described in Section 5.5.3.2 and Section 5.5.3.3 with the exception of the inclusion of the EES.

Mattamy Lands East, with the EES, can connect to the existing minor system in the Half Moon Bay South development. The Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015) has assessed the impact of connecting the Mattamy Lands East through the Half Moon Bay South

development and into Todd Pond from both a water quality and quantity perspective. This servicing strategy was deemed the preferred servicing solution for the Mattamy Lands East.

Mattamy Lands West, with the EES, would continue to connect to the trunk storm sewer on New Greenbank Road and the captured flows would need to be limited to the 880 l/s allocation as per the Barrhaven South MSS design sheet. As a result, flows in excess of 880 L/s up to the 1:100 year event must be detained on-site by means of street sag storage or a dry pond, or a combination of both. Should detailed design show that street sag storage is sufficient to detain the 1:100 year major overland flow then a dry pond may not be warranted.

5.5.4.3 Brazeau and Drummond Aggregate Extraction Areas

Existing Conditions Reports for both aggregate pit areas will need to be completed prior to their development. It is envisioned that both aggregate extraction areas will need to preserve pre-infiltration levels and which in turn will require that the proposed stormwater management servicing strategy incorporates measures to promote infiltration. The EES has been identified as a suitable strategy on urban development in the BSUEA to achieve distributed infiltration as required by the City. For private lots, infiltrating clean water roof runoff can achieve the required infiltration. At detailed design of these properties, the strategy to preserve pre-development infiltration rates will need to be reviewed with the Geotechnical Engineer once it is known what type of fill material was used to meet the minimum rehabilitation elevations.

5.5.5 Gallery Infiltration Approach

5.5.5.1 Minto Lands

Within the Minto Lands, an infiltration gallery could supplement the EES and/or replace part of the EES within Phase 2, on the western side of New Greenbank Road. It is envisioned that an infiltration gallery could be integrated to the footprint of the proposed spill-over dry pond located on the western side of the CDP boundary, adjacent to Barnsdale Road. This facility would service the local roads part of Minto's Phase 2 lands and would be bounded by New Greenbank Road to the east, the Park and Ride to the north, by Barnsdale Road to the south and by the western perimeter of the CDP. The total serviced area of the infiltration gallery would be around 12.5 ha.

Storm servicing of Phase 1 of the Minto Lands would be developed with the EES as described in Sections 5.5.4.1 and 5.8.2. Should monitoring of Phase 1's EES be inconclusive, then storm servicing of Phase 2 would be developed using an infiltration galley. The storm servicing approach with an infiltration gallery would need to incorporate a two pipe system; one system that would convey salt impacted runoff and the second conveying runoff free of chlorides. The latter system would drain to an infiltration gallery while the other system would service collector and arterial roads and would discharge to a downstream HDS for quality treatment. The proposed infiltration gallery would be located as part of the spill-over dry pond off Barnsdale Road and outside the CDP western boundary.

Potential infiltration volume would first be reviewed at the spill-over dry pond while considering design constraints such as infiltration rate of the native soils, available footprint of the spill-over dry pond, groundwater depth, hydraulics of the storm sewer system that would be connected to the infiltration gallery. Once the infiltration volume is assessed at the spill-over dry pond assuming a system comprised of manufactured module structures and surrounding granular material, an equivalent serviced area would be found based on 150 m^3/ha. From this assessment and the close review of the conceptual storm sewer system, a serviced area would be depicted.

It is envisioned that the EES would be approved as the measure that preserves infiltration for Minto's initial phase of development while carrying out flow monitoring concurrently to assess the performance of the EES.

5.5.5.2 Mattamy Lands East and Mattamy Lands West

The stormwater management strategy for the lands part of the Mattamy Lands East and Mattamy Lands West would not vary from that described in Section 5.5.3.2 and Section 5.5.3.3 with the exception of incorporating an infiltration gallery that would be sized to preserve infiltration levels.

Storm servicing for the Mattamy Lands East can be developed based on a connection to the existing minor system in the Half Moon Bay South development as assessed in the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015). This servicing strategy was deemed the preferred servicing solution for the Mattamy Lands East. The strategy and layout currently do not offer any lands dedicated to stormwater management in the subdivision to accommodate an infiltration gallery. Some of the proposed residential lots in the northern corner of the site near Manhole s720 would have to be dedicated as an infiltration facility should it be pursued at detailed design. In addition, smaller facilities would be required prior to connection to the external network at manholes s656 and s659 which would require further conversion of the residential lots into SWM blocks.

Storm servicing of the Mattamy Lands West with an infiltration gallery would maintain the same connection to the trunk storm sewer on New Greenbank Road and the captured flows would need to be limited to the 880 l/s allocation as per the Barrhaven South MSS design sheet. As a result, flows in excess of 880 L/s up to the 1:100 year event must be detained on-site by means of street sag storage or a dry pond, or a combination of both. The site of the dry pond could also accommodate an infiltration gallery. If the detailed design were to show that street sag storage is sufficient to detain the 1:100 year major overland flow then a dry pond may not be warranted, however land would still be required to host an infiltration gallery.

5.5.5.3 Brazeau and Drummond Aggregate Extraction Areas

It is envisioned that the proposed stormwater management servicing strategy will have to be developed to limit post-development flows to pre-development levels while preserving pre-infiltration rates. An infiltration gallery could be

accommodated into the land use development plan for the site to provide the required infiltration capacity. For private lots, infiltrating clean water roof runoff can achieve the required infiltration. At detailed design of these properties, the strategy to preserve pre-development infiltration rates will need to be reviewed with the Geotechnical Engineer once it is known what type of fill material was used to meet the minimum rehabilitation elevations.

5.6 Storm and Drainage Design Methodology

The design and evaluation of the proposed storm servicing solutions as outlined above were undertaken with the following design parameters for minor and major system analysis.

5.6.1 Runoff Coefficient

Surface runoff is triggered when precipitation exceeds the infiltration of landscaped surface and/or the initial abstraction of hard surfaces. To quantify the rate of runoff from the various surfaces, hydrological parameters representing different drainage characteristics must be calculated. The type of land cover and associated hydrological parameters are based on area weighting of the following:

Table 5-1: Land Cover Drainage Parameters

Land Cover	Impervious (%)	Runoff Coefficient	Draining to Pervious (%)
Commercial / Condo	93	0.85	0
Arterial / Collector Roads	86	0.80	0
Local Roads	71	0.70	0
Parks	29	0.40	100
Woodlots	0	0.20	100
Schools	79	0.75	0
Park and Ride	93	0.85	0
Single Family Residential	57	0.60	70
Townhouse Residential	64	0.65	70
Back to Back Residential	71	0.70	70
Blended Residential	66	0.66	70

Based on the above three (3) types of residential usages, a blended (average) Runoff Coefficient of 0.66 was used in the storm drainage analysis for the residential blocks.

Based on the recommendations noted in Section 5.4.5.2.2 of the OSDG, Runoff Coefficients or C-Factors associated with the various types of residential usages were based on actual impervious areas for the adjoining Quinn's Pointe subdivision

to the north-east of the site. Similar housing product is likely to be used on the study area development.

5.6.2 Trunk Sewer Sizing

Preliminary sizing of the storm sewer system is based on the road patterns shown on the demonstration plan (Figure 4-2) and intended to demonstrate the feasibility of the overall storm servicing strategy. The preliminary trunk storm sewer layout and associated drainage areas are shown on the following drawings:

- KS1: Servicing Key Plan - Conventional
- KS2: Servicing Key Plan - EES
- MST-1: Master Storm Drainage Plan - Conventional
- MST-2: Master Storm Drainage Plan - EES
- SWM-CONV: SWMFs - Conventional Storm System
- SWM-EES: SWMFs - EES Storm Sewer System
- MG1 and MG2: Master Grading Plans
- DT1: Detail Sheet

Based on the above information, storm sewer design sheets have been prepared and included in Appendix F. The proposed storm sewers along the various road types have been sized in accordance with the level of service identified in Section 5.6.1. The rate of capture along the arterial road was set to the prescribed 1:10 year design event in accordance with the OSDG while collector and local roads were set to a 1:5 year design event, which meets and exceeds the OSDG for both roadway types.

Where required, storm sewers were upsized to accommodate the freeboard to the HGL requirements as per the hydraulic modelling assessment. In addition, the HGL requirements meant that one storm sewer section will require to be constructed invert to invert rather than the conventional obvert to obvert connection. This deviation from normal standards is requested from the City.

The Storm Sewer Design Sheets included in Appendix F were developed to incorporate the BSUEA lands as well as the Quinn's Pointe system as the captured flow from the latter system impacts the performance of the storm sewer system connecting to the Greenbank Road trunk system. In addition, the storm sewer design sheets account for overland flow from external areas which will remain undeveloped and flow uncontrolled towards the BSUEA and be captured into the minor system via ditch inlets.

The Quinn's Pointe storm sewer system was originally designed in 2015 based on a storm capture of 1:5 year. Since then, the level of service for local streets has been reduced in the OSDG from the 1:5 year to a 1:2 year capture. Given that proposed servicing depicted on Drawings KS1 and MST-1 shows that the area from the BSUEA lands serviced by the existing Kilbirnie Road 750 mm diameter

storm sewer (i.e., pipe reach between MH710-MH720) has increased from 2.3 ha (per 2015 design) to 4.8 ha, the Storm Sewer Design Sheets for the Quinn's Pointe subdivision was revised based on a 1:2 year capture. With the 1:2 year capture criteria, the minimum freeboard of 300 mm during the 1:100 year storm (3 hour and 24 hour) is met everywhere in Quinn's Pointe and the BSUEA (Minto Lands) as per Table 5-5 and Table 5-11 below, and free flow occurs in the Quinn's Pointe minor system in the 1:2 year event. During a significant event, runoff exceeding the above-noted level of service would result in overland flow, which would be conveyed along the major overland system. As layout revisions are anticipated in the future as plans of subdivision are developed, refinements to the design of the systems are expected. The plans of subdivision should maintain consistency with the drainage boundaries as much as possible since this information has been used to size the SWMF blocks and EES.

5.6.3 Roadway Sag Storage

Due to falling topography when moving easterly, the Master Grading Plan (Drawing MG1) was developed to provide a route to safely convey major overland flow while minimizing earth works. In order to fulfill these objectives, grading of the major overland system is to be carried out following a saw-tooth profile with low points introduced along the major overland system when topography will allow. Since detailed design will dictate the location and extent of the roadway sag depths, modelling was carried out assuming an on-site storage of 50 m^3/ha which is deemed conservative based on the storage achieved in Quinn's Pointe having similar topography. Roadways with flatter slopes will generate greater storage capacity, while those that are steeper will have limited storage capacity.

The design of the major overland system will allow runoff to be stored in the roadway depressions prior to its capture by the catch basins and inlet control devices (ICD). During infrequent events, runoff in excess of the rate of capture of the minor system and roadway sag storage will cascade along the major overland system.

5.6.4 Storm Dual Drainage Analysis

5.6.4.1 Modelling Software

The dual drainage analyses presented herein were carried out using the PCSWMM software platform. This includes the hydrology of the study area as well as the preliminary minor and major system analyses and infiltration system hydraulics. PCSWMM is based on the EPA SWMM engine in a GIS environment.

The PCSWMM dual drainage model will provide preliminary confirmation of the overland flow depths along the collector and arterial roads, feasibility of the proposed sewer sizing in terms of HGL, block sizes for SWMFs, and capacity of the infiltration system. Model inputs and results are contained in Appendix G.

5.6.4.2 Model Assumptions and Methods

The dual drainage analysis uses a dynamic simulation to calculate the hydrology and hydraulics of the major and minor systems. The model has been developed using:

- City of Ottawa IDF data Chicago Storms applied across catchments with characteristics area weighted from Table 5-1;
- Sag storage for each subcatchment represented as storage nodes with a basic 50 m³/ha applied across all catchments with the exception of Commercial and ICI blocks where on-site storage was assumed to be sufficient to self-contain the 1:100 year flow;
- A 1:5 year and 1:10 year design capture for the local/collector roads and arterials, respectively;
- Exit losses are applied at the downstream end of each sewer section based on the OSDG; and,
- HGL should be kept at least 2.3 m below the proposed grades shown on the preliminary grading plan to accommodate an underside of footing which incorporates basements, approximately 2 metres, as well as prescribed minimum freeboard of 300 mm.

In addition, the following assumptions were used for the modelling of the EES along local roads:

- An average storage of 0.75 m³/m (950 mm deep envelope) was utilized and combined with an exfiltration rate based on the hydraulic conductivities found during geotechnical assessment with the required safety factor reduction, which was simulated as a storage node in the minor system. This configuration within residential areas has proven that the EES can capture the 95th percentile, equivalent to a 22 mm storm event. It was also assumed that ICI blocks would include an EES sized to solely capture rooftop flow up to a 22 mm storm.

5.6.4.3 Interaction with Other Models and External Areas

Due to existing servicing in Quinn's Pointe, there is an interaction between Quinn's Pointe and the BSUEA. As a result, the minor system model developed for Quinn's Pointe was integrated to the BSUEA model.

5.7 Analysis of Conventional System

5.7.1 BSUEA Site Wide Infiltration with Conventional System

A water budget analysis was carried out as part of the Existing Condition Report (Section B6, Appendix B). This analysis revealed that pre-development infiltration across the BSUEA accounted for 40% of the total precipitation based on long-term simulations. The simulated post-development water budget analysis described in Section 5.4.4 has been carried out to evaluate the post-development infiltration

should storm servicing rely solely on a conventional system. Table 5-2 summarizes the water budget simulation results under both pre- and post-development conditions. As shown below, servicing of the BSUEA lands with a conventional system will achieve an infiltration of 22% which is less than that under pre-development conditions. Consequently, the conventional system cannot preserve the pre-infiltration levels.

It should be noted that this analysis has excluded the Brazeau and Drummond aggregate areas, which have been assumed to integrate measures to promote infiltration and preserve pre-infiltration rates along both properties separately from the remaining BSUEA.

Table 5-2: BSUEA Conventional System Water Budget Results

Water Budget Component	Annual Average Depth (mm)	Budget (%)	Existing Condition Budget (%)
Precipitation	844	100%	100%
Evapotranspiration	231	27%	60%
Infiltration	189	22%	40%
Surface Runoff	413	49%	0%

5.7.2 Minto Lands

5.7.2.1 Major System Cascading and Ponding Levels

The elevations of the major system nodes are shown in Table 5-3 and Table 5-4. As shown in these tables, there is no ponding in the 1:5 year event or 1:10 year event for local/collector roads and arterial roads, respectively, while the depth of flow along the major system is maintained to or below 350 mm during the 1:100 year event.

5.7.2.2 Minor System HGL

An HGL analysis was conducted along the minor system to demonstrate that the minimum prescribed freeboard of 300 mm is achieved. Simulation results have been summarized in Table 5-5 based on assumed USF elevations of 2 m below the surface. Table 5-5 shows that during the 1:100 year event the system provides the required 300 mm minimum freeboard along the trunk sewers. During the climate change event, the simulated HGLs remain below the USF.

5.7.2.3 Water Quality

Under the conventional storm system, water quality treatment for the Minto Lands will be provided through the use of two (2) wet ponds abutting Greenbank Road as depicted on Drawing SWM-CONV. These facilities are sized to provide water quality and quantity control prior to discharge into the 1800 mm outlet from Quinn's Pointe that discharge into the Greenbank Road trunk sewer system. Given that the capacity into the Greenbank Road trunk storm sewer system will be shared by Quinn's Pointe, Minto's BSUEA lands and the Greenbank Road ROW, a high level concept for the facilities is shown on Drawing SWM-CONV.

As previously noted, the Corrigan facility was sized to achieve an 80% TSS removal for the Quinn's Pointe subdivision.

As a result, Quinn's Pointe runoff does not require any quality control. Hence, the volume requirements identified in Table 5-6 for Wet Pond 1 is solely based on Minto's lands part of the BSUEA and excludes Quinn's Pointe while Wet Pond 2 is based on the remainder of Minto's lands and the southern section of Greenbank Road ROW. Calculations carried out for the sizing each of the pond's permanent pool volume is included in Appendix G.

Table 5-6: Minto Conventional System Water Quality Volumes

Parameter	Wet Pond 1	Wet Pond 2
Total Drainage Area (ha)	29	58
Average Imperviousness (%)	70%	64%
Water Quality Volume Required / ha (m^3/ha)	225	212
Minimum Extended Detention Storage (m^3)	1,160	2,330
Volume of Permanent Pool required (m^3)	5,360	9,990
Permanent Pool Volume Provided (m^3)	11,166	11,960

5.7.2.4 Pond Operation

The proposed end-of-pipe wet ponds abutting Greenbank Road, as depicted on Drawing SWM-CONV (Wet Pond 1 and Wet Pond 2), were sized at a high level to serve a dual purpose: i) meet an 80% TSS removal for all of the BSUEA lands (Minto Lands) as well as for an additional ROW section of Greenbank Road (up to Barnsdale Road), and ii) limit post-development flows from both the BSUEA lands

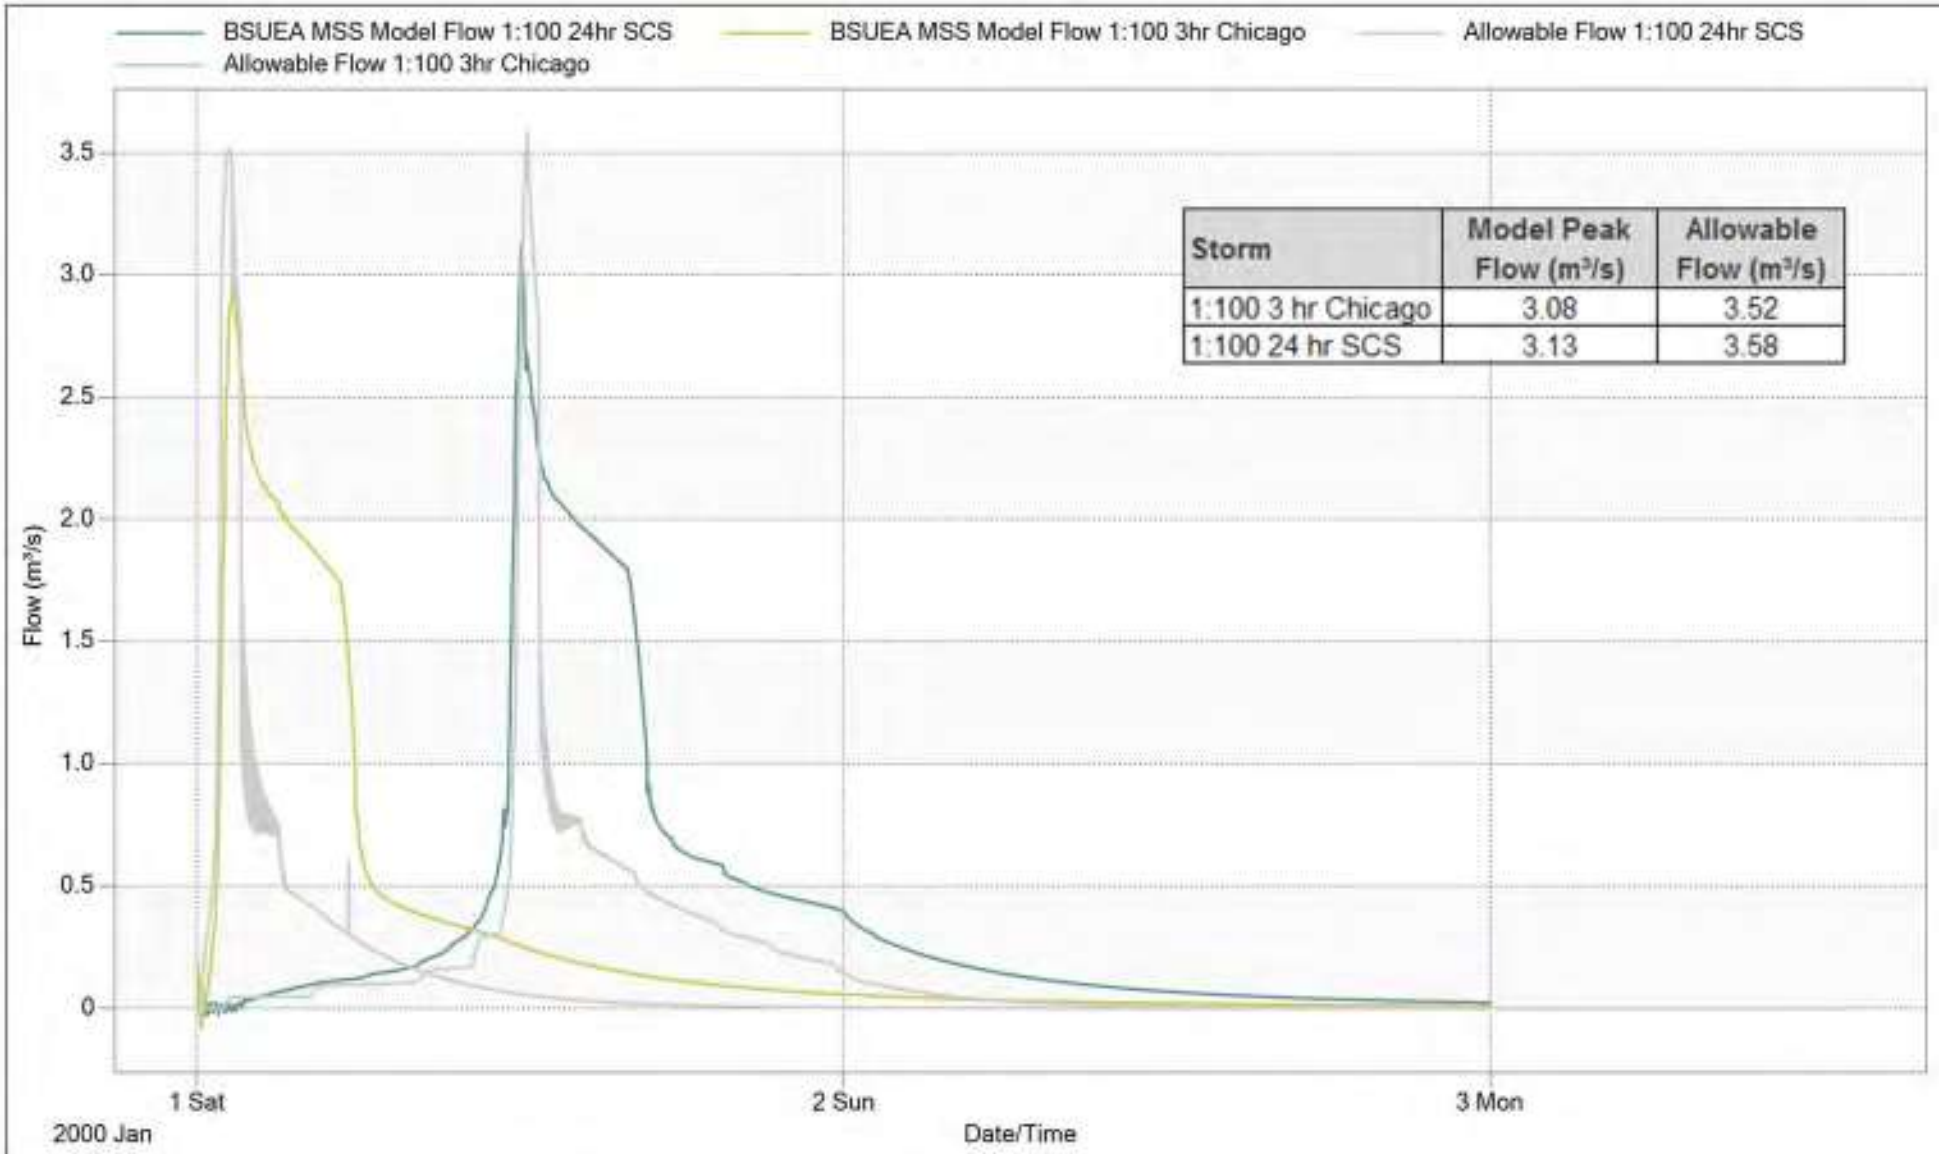
and Quinn's Pointe to ensure that the 1:100 year prescribed flow of 3,580 L/s allocated to the trunk storm sewer leading to the Corrigan Pond at Manhole MH102 at the intersection of Greenbank Road and Kilbirnie Drive.

In order to reduce headlosses, runoff from Wet Pond 1 discharges via two (2) double ditch inlets which connect into a new sewer loop constructed off the existing trunk storm sewer outlet for the Quinn's Pointe subdivision. The double ditch inlets allow both discharge of the pond and controlled surcharging of the Quinn's Pointe minor system into Wet Pond 1 when the conveyed flows exceed the capacity of the downstream orifice plate. To achieve the prescribed flow of 3,580 L/s, the combined outflow from Wet Pond 1 and Quinn's Pointe is controlled through a 675 mm diameter orifice plate on the downstream end of the Quinn's Pointe storm sewer, and upstream of the connection with the Greenbank Road trunk storm sewer. The flow allocation was identified in the IBI's analysis which was part of JLR's Servicing Brief (2014) as described in Section 5.3.1.

A comparison of the trunk sewer hydrographs was carried out between those at the downstream end of the combined model of the BSUEA and Quinn's Pointe with those in the same sewer section in the IBI analysis. The graphical comparison (Figure 5-5) shows that peak flow rates of the proposed servicing under the conventional system strategy is consistent with or below the peak flow rates in the IBI analysis. In addition, the analysis of the existing Greenbank Road trunk storm sewer contained in the model shows that during the 1:100 year storm event the Q/Qcap value in the storm sewer is just below 65% indicating that there is additional residual capacity available.

The required extended detention volume in Wet Pond 1 will need to be controlled without hindering the surcharge of flows from Quinn's Pointe through the two double ditch inlets. To achieve the required extended detention storage, a berm has been placed in the facility around the two double ditch inlets. This proposed configuration will create a two (2) cell pond with the larger of the cells on the upstream side of the berm being sized to provide containment and slow release of the extended detention storage. The additional cell on the downstream side, near the existing 1800 mm diameter storm sewer outlet will contain the double ditch inlets.

Frequent flows from BSUEA (Minto Lands) will first enter Wet Pond 1 and will be directed through the plunge pool/sedimentation forebay for pre-treatment. From that point, flows would then be conveyed along a flow path that has been extended by means of low flow berms. Frequent flows would fill-up the extended detention storage of the containment cell, set between elevations of 95.0 m and 95.5 m, and would be controlled by means of an orifice located within the berm of the containment cell set at the Normal Water Level elevation of 95.0 m. This restrictor, sized as part of the detailed design of the facility, would be responsible for providing the 24 hour drawdown of the extended detention storage of 780 m^3. By adopting this configuration, frequent flows from BSUEA (Minto lands) would receive treatment while allowing Quinn's Pointe runoff to be conveyed freely to the Greenbank Road trunk sewer system.



Storm	Model Peak Flow (m^3/s)	Allowable Flow (m^3/s)
1:100 3 hr Chicago	3.08	3.52
1:100 24 hr SCS	3.13	3.58

FIGURE 5-5

During less frequent events where flows from Quinn's Pointe exceed the conveyance capability of the 675 mm diameter orifice, surcharge would be encountered in the system where flows from Quinn's Pointe would begin to back-up and fill Wet Pond 1 from the new sewer loop and have reverse flow through the double ditch inlets. Filling of the downstream cell would continue until the volume of the cell is exceeded. Once an elevation of 95.50 m is reached, the downstream cell would overtop the berm into the containment cell. When this situation occurs, flows beyond the water quality event would then be combined and the facility would perform as a 1 cell pond. Once capacity in the existing 1800 mm diameter storm outlet is available (controlled via the 675 mm diameter orifice plate), runoff would then flow through the double ditch inlets. Once the water level in Wet Pond 1 recedes below 95.50 m, runoff from the containment cell would be released slowly through the restrictor until reaching the Normal Water Level of 95.0 m.

Wet Pond 2 has been conceptually configured as a traditional wet pond that incorporates a plunge pool/sedimentation forebay, permanent pool, extended detention storage as well as quantity storage. The facility has been set with a normal level of 95.6 m with extended detention storage of 1.2 m (refer to Drawing SWM-CONV for details). A restrictor will be set at the Normal Water Level of 95.60 m and will be sized at detailed design to achieve the drawdown time of 24 hours. As previously noted, Wet Pond 2 was sized for Minto's lands and also for the southern extension of Greenbank Road ROW totalling 1.67 ha (up to Barnsdale Road). In terms of quantity control, Wet Pond 2 will be controlled by means of a 450 mm diameter restrictor.

The spill-over dry pond located outside the CDP was sized to capture the major overland flow while releasing flows to the available capacity in the downstream storm sewers. Table 5-7 summarizes the various parameters used in the sizing of the wet ponds and spill-over dry pond while Drawing SWM-CONV provides the arrangement of the facilities and connections to the proposed storm sewer system.

Table 5-7: Minto Conventional System Pond Parameters and Results

Pond Parameter	Wet Pond 1	Wet Pond 2	Western Spill-over Pond
Pond Invert (m)	93.5	94.1	100
Permanent Pool Elevation (m)	95	95.6	-
Modelled Release Rate (m^3/s)	1.65	0.2	0.08

Sediment Drying Area Required (m^2)	960	1,500	n/a

5.7.3 Mattamy Lands East

As part of the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015), a major and minor system analysis was undertaken by Stantec using DDSWMM and XPSWMM, respectively for the Half Moon Bay South subdivision incorporating the Mattamy Lands East. These analyses were carried out under: i) interim conditions, - where undeveloped lands across the BSUEA are naturally draining overland, and ii) under ultimate conditions - with the Mattamy Lands East developed and draining to the Todd Pond.

The proposed servicing where the Mattamy Lands East would be connected to the adjacent services would only impact the Half Moon Bay South development. A summary of the analysis undertaken by Stantec is extracted and presented below. The full report is copied on the data disc included in Appendix N.

5.7.3.1 Major System Ponding Levels

The DDSWMM major overland analysis has shown 1:100 year ponding depths less than 350 mm deep, within both the Mattamy Lands East lands and the wider Half Moon Bay subdivision, thereby meeting the City requirements. The DDSWMM segments and associated ponding depths are shown in Appendix H, Table G-1.

5.7.3.2 Minor System HGL

An HGL analysis of the minor system was carried out as part of the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015). This analysis showed that the 1:100 year HGL achieves the 300 mm freeboard to the USF within both the Mattamy Lands East (Appendix H, Table G-2) and the wider Half Moon Bay Subdvision (Appendix H, Table G-3). Under the Climate Change stress test event, the HGL does not rise above the USF.

The results for the Mattamy Lands East lands minor system were not included in the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015) however the modelling undertaken for the report did include the Mattamy Lands East area as developed and the results for this area were extracted from the modelling.

5.7.3.3 Quality Control

The assessment of water quality control for the Half Moon Bay South subdivision, including the Mattamy Lands East portion, was included in the work undertaken by J.F. Sabourin & Associates in April 2015 as the Todd Pond Model Keeper.

According to the Todd Pond Model Keeper Analysis Re-Assessment of Existing System Capacity (JFSA, 2015), adding the Mattamy Lands East to the current serviced area of the pond would result in an area of 113 ha at a weighted average imperviousness of 54%. In order to achieve an enhanced protection (80% TSS removal) for the overall catchment, a permanent pool volume of 187 m³/ha is required or a total volume of 16,670 m³ (excluding the 40m³/ha of extended detention storage). The reported available permanent pool volume in the pond, at a water level of 89.650 m, is 23,716 m³. Therefore, there is sufficient capacity to provide water quality control for the Mattamy Lands East in the Todd Pond.

Based on the Todd Pond Model Keeper Analysis Re-Assessment of Existing System Capacity (JFSA, 2015), the required extended detention storage for the 113 ha is 4,520 m³ and the available extended detention storage in the pond is 21,015 m³. Therefore, there is sufficient extended detention storage in the facility for the Mattamy Lands East.

5.7.4 Mattamy Lands West

5.7.4.1 Quantity Control

The Mattamy Lands West area will need sufficient on-site storage to prevent the 1:100 year major overland flow from reaching New Greenbank Road. On-site storage will be a combination of street sag storage that will be complemented by a spill-over dry pond to accommodate the 1:100 year major overland flow. Based on the Demonstration Plan (Figure 4-2), the area for these lands is 3.6 ha and has a total imperviousness of 65.3 %. Based on an assumed street sag storage of 50 m³/ha, a major system depth limit of 350 mm and a 1:5 year capture rate of 780 L/s, the 1:100 year simulation results showed that to maximize the street sag storage and prevent cascading onto New Greenbank Road, there is a need for an additional 130 m³ spill-over dry pond as depicted on Drawings SWM-CONV and SWM-EES. Simulation undertaken assumed a dry pond release rate of 100 L/s which combined to the capture rate of 780 L/s met the prescribed flow from the site of 880 L/s (per the allowable release rate of the Draft BSMSSA, Stantec, 2014).

Should detailed design show that the street sag storage can be increased to 90 m³/ha, modelling has showed that there would not be a need for a spill-over dry pond. Detailed design including grading of the Mattamy Lands West will dictate whether a spill-over dry pond is required.

5.7.4.2 Quality Control

The permanent pool of the Clarke Pond was sized based on a drainage area of 119.9 ha at an average imperviousness of 68% (refer to the Clarke Pond Design Brief, JFSA, 2015). By altering the pond catchment characteristics for Mattamy

Lands West from 8 ha of undeveloped to the 3.6 ha of urban development as per the demonstration plan would yield a drainage area of 116 ha at an average imperviousness of 73%. In accordance with Table 3.2 of the MOE SWMPDG, a water quality volume of 229 m³/ha is required for 80% TSS removal, which equates to a permanent pool of ±22,000 m³, excluding the 40 m³/ha of extended detention storage. The Clarke Pond has been designed with a permanent pool of 22,868 m³, and therefore has sufficient capacity to provide water quality control for the Mattamy Lands West.

5.7.5 Brazeau and Drummond Aggregate Extraction Areas

Due to timing of this development, the Brazeau and Drummond aggregate extraction areas have been modelled as two (2) separate drainage areas. In order to restrict the post-development peak flows to the required constraint of 1,300 L/s (Section 5.3.4) at the downstream outlet, an average storage of 365 m³/ha is required across the site. The storage can be provided in a combination of rooftop, surface ponding, ponds or underground.

Assuming that the aggregate areas would be serviced via two (2) separate SWMFs (Section 5.5.3.4), the total on-site quantity storage requirement for the sites is 8,640 m³ on Brazeau lands and 7,300 m³ on Drummond lands.

The outlet trunk storm sewer for the two SWMFs servicing the Aggregate Extraction Areas has been sized based on the allowable release rates from the two sites as per Section 5.3.4. This outlet trunk storm sewer, proposed along Borrisokane Rd, was sized as the minimum diameter (825 mm diameter at 0.17% slope) required to intercept the flow from the two SWMFs to the edge of the 1:100 year floodplain of the Jock River, at which point it will be conveyed in a proposed open watercourse (i.e., Borrisokane roadside ditch) to the Jock River. In order to have sufficient cover, the pipe may have to be constructed under the Borrisokane Road shoulder rather than under the ditch centreline. Should additional lands be required to drain to this outlet trunk storm sewer, such as the ROW of Borrisokane Road and/or adjacent properties, then the 825 mm dia. outlet trunk will need to be resized accordingly at the detailed design stage.

In terms of the on-site storm sewer system required to service the Brazeau and Drummond Aggregate Extraction Areas, a high level gravity sewer system free of submergence was developed based on a normal water level (NWL) assigned to each of the SWMFs. The NWL for the Drummond SWMF and the Brazeau SWM facility were conceptually set at elevation 94.0 m and 94.5 m, respectively, based on the conceptual invert of the 825 mm dia. Borrisokane Rd outlet trunk pipe. For the Brazeau lands, the most upstream storm sewers would vary from 98.0m to 99.5m depending on crossings of the sanitary sewers. Based on a projected cover of 3.0m over the 99.5 m obvert, a grade rise up to 101.5m in the westerly half of the property would be required. For the Drummond lands, the most upstream storm sewer obvert was estimated at approximately 97.65 m, assuming the sanitary sewer would cross above the storm sewers. Based on a projected cover of 3.0m over the 97.65 m obvert, a grade rise up to 100.65 m in the easterly half of the property would be required. Refer to Section 6.3.1 for additional information on required reinstatement elevation for the Aggregate Extraction Areas.

5.8 Analysis of EES Results

5.8.1 BSUEA Site Wide Infiltration with EES

A water budget analysis was carried out as part of the Existing Condition Report (Section B6, Appendix B). This analysis revealed that pre-development infiltration across the BSUEA accounted for 40% of the total precipitation based on long-term simulations. Based on the post-development simulation results, the water budget for the overall BSUEA lands is shown in Table 5-8 below and compared in the table with the existing conditions water budget. The use of the EES along the local road network within the BSUEA lands achieves an infiltration of 44% which is greater than under existing conditions, which shows that infiltration within ±10% of existing is achievable. It should be noted that this analysis has excluded the Brazeau and Drummond properties which have been assumed to integrate measures to promote infiltration and preserve pre-infiltration rates along both properties separately from the remaining BSUEA. Further refinements to the high level infiltration concept, including sizing of the EES, can be investigated during detailed design.

Table 5-8: BSUEA EES Water Budget Results

Water Budget Component	Annual Average Depth (mm)	Budget (%)	Existing Condition Budget (%)
Precipitation	844	100%	100%
Evapotranspiration	231	27%	60%
Infiltration	377	44%	40%
Surface Runoff	225	27%	0%

5.8.2 Minto Lands

5.8.2.1 Major System Cascading and Ponding Levels

The simulated elevations along the major overland system nodes are shown in Table 5-9 and Table 5-10. There is no ponding during the 1:5 year event or 1:10 year event for local/collector roads and arterial roads, while the depth of flow along the major system is maintained to or below 350 mm during the 1:100 year event.

5.8.2.3 Water Quality

Infiltration systems are known to be an effective measure to meet the fish habitat protection level as define in the MOE SWMPDG. Table 3.2 of the SWMPDG stipulates that infiltration systems can provide for water quality treatment and up to 80% TSS removal provided that the system is sized with sufficient storage. The requirements for infiltration storage to achieve 80% TSS removal are set out in Table 5-12 below. As can be seen from Table 5-12, the provision of EES within the Minto Lands achieves water quality protection for the lands serviced by the EES. As a result, no further water quality treatment is required.

Table 5-12: Minto EES Water Quality Volumes

Parameter	Value
Total EES Drainage Area (ha)	36.6 ha
Average Imperviousness (%)	66%
Water Quality Volume Required / ha (m^3/ha)	34 m^3/ha
Total Storage Volume in EES (m^3)	5,315 m^3
Total Storage Volume in EES / ha (m^3/ha)	145 m^3/ha

For the remaining of the Minto Lands not serviced by EES (i.e., collector and arterial) but draining to a conventional system, the water quality treatment will be provided by a HDS prior to discharge into the dry pond. The HDS unit is the preferred quality control measure to meet an 80% TSS removal; during frequent events, runoff from the conventional sewer system will be insufficient to maintain flow in a wet pond which could lead to algae bloom and mosquito breeding grounds. Based on the conceptual Storm Sewer Design Sheet under the EES servicing strategy (Appendix F), an AxC ratio of 16.13 is tributary to the HDS. It is

recommended that a commercially distributed unit be selected at detailed design and that design flows be provided to the manufacturer for sizing.

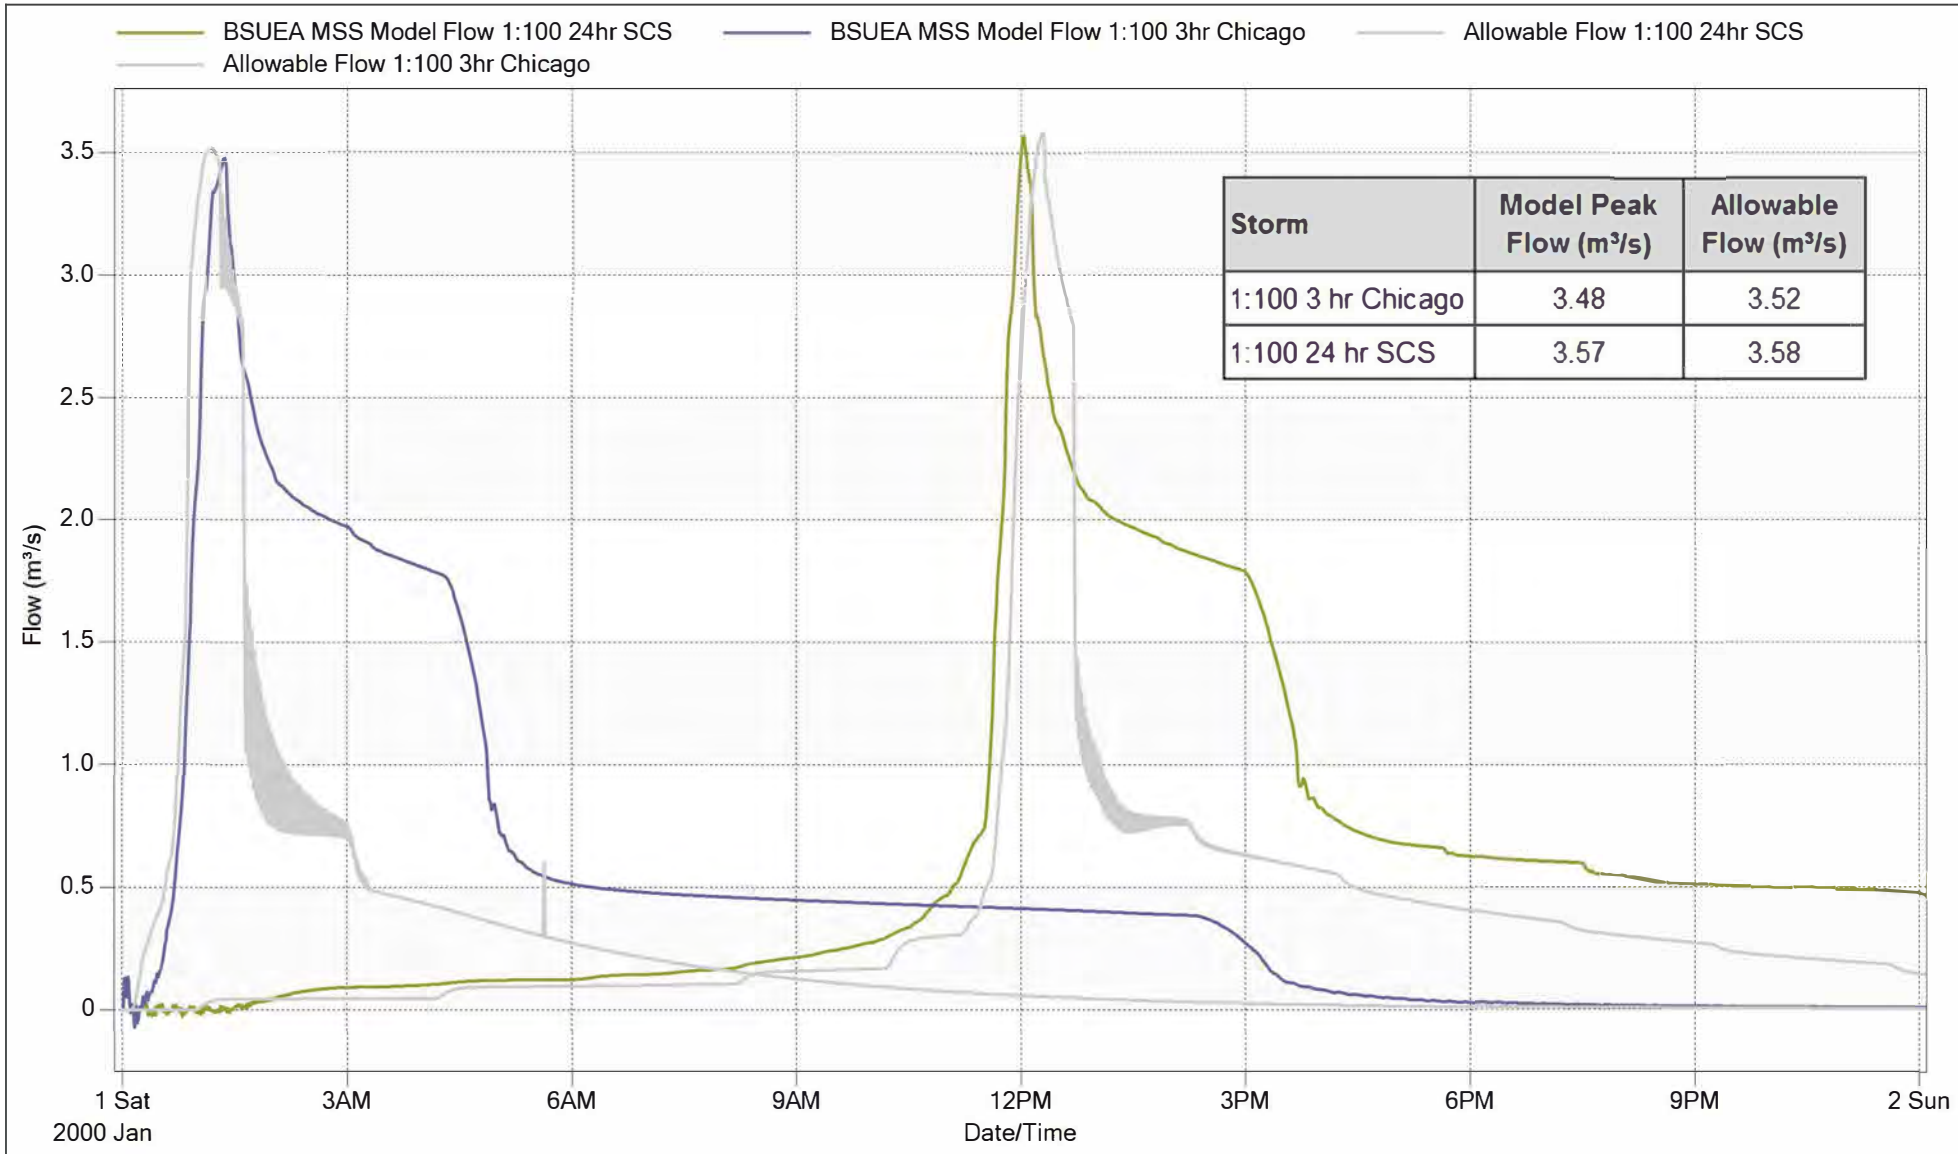
5.8.2.4 Pond Operation

The proposed two (2) dry ponds abutting Greenbank Road are referred to as Dry Pond 1 (northern Dry Pond) and Dry Pond 2 (southern dry pond) as depicted on Drawing SWM-EES. These facilities were sized to limit the post-development flows under the 24 hour - SCS 1:100 year design storm to the prescribed flow of 3,580 L/s allocated to the trunk storm sewer leading to the Corrigan Pond at Manhole MH102 at the intersection of Greenbank Road and Kilbirnie Drive. The above flow allocation also includes the Greenbank Road ROW (from the Barnsdale Road intersection to MH820), an existing undeveloped area of 3.6 ha located east of Greenbank Road, and portions of Quinn's Pointe that discharges at MH820 and MH102. The flow allocation was identified in the IBI servicing report as described in Section 5.3.1.

A comparison of the trunk sewer hydrographs was carried out between those at the downstream end of the combined model of BSUEA and Quinn's Pointe with those in the same sewer section in the IBI analysis. The graphical comparison (refer to Figure 5-6) shows that peak flow rates of the proposed servicing under the EES strategy is consistent with or below the peak flow rates in the IBI analysis. In addition, the analysis of the existing Greenbank Road trunk storm sewer contained in the model shows that during the 1:100 year storm event the Q/Qcap value in the storm sewer is just below 75% indicating that there is additional residual capacity available.

The dry pond discharges through two (2) double ditch inlets which connect into a new sewer loop constructed off the existing trunk storm sewer outlet for the Quinn's Pointe subdivision. The double ditch inlets serve as the pond's outlet and provide a connection that will result in the surcharging of the Quinn's Pointe minor system in a controlled manner vertically into the pond. The connection is proposed to ensure that the invert of Pond 1 is set above the groundwater level in that area. The discharge into the Greenbank Road trunk storm sewer is controlled through an orifice plate on the downstream end of the Quinn's Pointe storm sewer downstream of the pond connection and prior to the connection with the Greenbank Road trunk storm sewer.

In regard to the western spill-over dry pond, its release rate was set to maximize the residual capacity in the downstream storm sewers while meeting the minimum drawdown time of 24 hours as prescribed by the MOE in the SWMPDG. Should the restrictor be susceptible to clogging due to its size, it can be increased at detailed design which would reduce the drawdown time. A summary of key pond parameters are in Table 5-13 below while Drawing SWM-EES presents the Conceptual Pond design.



Storm	Model Peak Flow (m³/s)	Allowable Flow (m³/s)
1:100 3 hr Chicago	3.48	3.52
1:100 24 hr SCS	3.57	3.58

5.8.3 Mattamy Lands East and Mattamy Lands West

The Mattamy Lands East was modelled at the conceptual level as part of the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015) while the minor system of Mattamy Lands West was included in the Draft BSMSSA, Stantec, 2014. Neither of these Reports included an assessment of EES within the storm minor system.

Including the EES within these areas would not alter the stormwater management approach as neither of the Mattamy Lands requires additional water quality control and the MSS designs do not affect major system storage requirements. The use of EES in Mattamy Lands East, however, may improve the downstream HGLs in the Half Moon Bay South subdivision and areas draining to the Todd Pond as exfiltration of clean runoff into the underlying groundwater and esker would be promoted resulting in a reduction in the flow and increase in available capacity in the conventional sewers.

5.8.4 Brazeau and Drummond Aggregate Extraction Areas

The EES has been identified as a suitable strategy on urban development in the BSUEA to achieve distributed infiltration as per the recommendations of Paterson's Existing Conditions Report. Assuming that both aggregate extraction areas are developed as residential, infiltrating clean runoff from local roads can achieve the required infiltration. Alternatively, infiltration galleries could also supplement or replace part of an EES. At detailed design of these properties, the strategy to preserve pre-development infiltration rates will need to be reviewed in consultation with the Geotechnical Engineer once it is known what type of fill material was used to meet the minimum rehabilitation elevations.

5.9 Analysis of Gallery Results

5.9.1 BSUEA Site Wide Infiltration with Gallery

The infiltration gallery servicing Minto's Phase 2 Lands would need to be designed with an equivalent infiltration capacity of that of the EES in order to achieve a water balance similar to that shown in Section 5.8.1. The water balance under the EES would achieve within 10% of the pre-development infiltration under post development conditions. Under the EES strategy, it was considered that comparable infiltration would be achieved pre- to post-development conditions while excluding the aggregate extraction areas that would be assessed on their own.

5.9.2 Minto Lands

To maintain the same infiltration rate as achieved under the EES servicing approach, the same unit storage volume would have to be accommodated by the infiltration gallery proposed under this servicing alternative. Based on a serviced area of ±13.5 ha (Figure 5-7) and a required storage volume of 145 m^3/ha, the gallery would have to provide an infiltration volume of ±1,870 m^3. The proposed spill-over dry pond could incorporate an infiltration gallery as it is a shallow facility and located in a low-lying area. The spill-over dry pond depicted on Drawing KS2 has a footprint of ±1,200 m^2 and considering perimeter access roads, a block of ±1,350 m^2 would be required to capture major overland flow. The dry pond footprint is, therefore, consistent with the storage volume requirements of the infiltration gallery. This high-level assessment was completed based on the provision of the Storm Tech storage chambers as the infiltration gallery infrastructure. Other equivalent products would be reviewed at detailed design once the exact storage volume and block requirement is found.

Similar to the EES, storage of 145 m^3/ha in an infiltration system is greater than the 34 m^3/ha required under the MOE SWMPDG to achieve 80% TSS removal. Therefore, no further water quality treatment would be required under the infiltration gallery approach. However given that there is a potential for the infiltration gallery to deteriorate with a build-up of sediment, some level of pre-treatment would extent the lifespan of the facility.

5.9.3 Mattamy Lands East and Mattamy Lands West

The Mattamy Lands East was simulated at the conceptual level as part of the Half Moon Bay South – Phase 4 Stormwater Management Report (Stantec, 2015) while the minor system of Mattamy Lands West was included in the Draft BSMSSA, Stantec, 2014. Neither of these Reports included an infiltration gallery in the stormwater management strategy.

Incorporating an infiltration gallery within these areas would not impact the stormwater management servicing approach as neither of the Mattamy Lands requires additional water quality control. The use of an infiltration gallery in Mattamy Lands East, however, may improve the downstream HGLs in the Half

Moon Bay South subdivision as exfiltration of clean runoff into the underlying groundwater and esker would be promoted resulting in a reduction in the flow conveyed to the Todd Pond which in turn would increase the available capacity in the conventional sewers. However, a block for this purpose would need to be dedicated in the subdivisions to accommodate an infiltration gallery.

5.9.4 Brazeau and Drummond Aggregate Extraction Areas

The use of an infiltration gallery has not been assessed in these areas. The aggregate extraction areas will need to preserve pre-infiltration rates. The strategy to preserve pre-development infiltration rates will need to be reviewed in consultation with the Geotechnical Engineer once it is known what type of fill material was used to meet the minimum rehabilitation elevations.

5.10 Impact of Servicing

5.10.1 Groundwater

Groundwater levels were monitored as part of an extensive monitoring program developed by Paterson. The extent and results have been summarized in their Existing Conditions Report (July 5, 2017). This Report documents the monitoring that spanned between 2015 and 2016.

Data reported in the Existing Conditions Report showed a decrease in the groundwater levels when compared to information compiled in 2011 and 2014 as part of the Quinn's Pointe Subdivision. The higher groundwater levels recorded in 2011 and 2014 resulted from surface water ponding over a clay lens immediately south of Quinn's Pointe. Surface water ponding was created by fill material that was placed on the Quinn's Pointe property which caused a barrier to sheet flow and temporary ponding over the clay area. The boreholes were placed adjacent to the ponded zone that produced artificially high groundwater levels due to the temporary perched water. Once the fill material on the Quinn's Pointe development was removed, the perched water was able to dissipate. It is the opinion of the hydrogeologist that groundwater measurement differences are not attributed to the construction of servicing in the adjacent Quinn's Pointe development but more so as a result of site alteration.

During the preparation of the Existing Conditions Report, it was acknowledged that sewers installed below the groundwater levels (2015 and 2016) could be designed at detailed design with mitigating measures. However, the City also acknowledged that compacted granular 'A' along sewers installed within the groundwater would provide an impediment to groundwater flow provided that the native material exhibits a greater hydraulic conductivity. Should sewers be installed within areas of high groundwater table with lower hydraulic conductivities than compacted granular 'A', the following mitigation measures could be utilized;

- Concrete pressure pipe (CPP);
- Higher class PVC pipes;
- Higher percentage silica fume in maintenance hole structures; and

- Cretex seals in maintenance holes.

It should be noted that at some locations along the minor system in the EES servicing option, the groundwater table is estimated to approach the underside of the EES temporarily during periods of high groundwater. Guidance on the EES recommends that there is sufficient clearance from the underside of the EES to the groundwater table, which is achieved during normal operations. The EES has been designed to store runoff from up to the 22mm rainfall event. Storage of up to the 22 mm rainfall event would still be possible if there is a temporarily high groundwater table and infiltration would continue when groundwater levels lower.

5.10.2 Impact of Servicing on Municipal Drains

The review of topography had revealed that parts of the BSUEA lands are tributary to the Thomas Baxter (Dynes Branch) Municipal Drain and to the east, the Hawley Municipal Drain, which outlets to the Hawkins Municipal Drain. Tables 5-3 and 5-5 of the Existing Condition Report (Appendix B) summarized the tributary area and simulated flows to boundary culverts leading to both Municipal Drains. As reported in these tables, culverts BDR-C3 and BDR-C4 were found to convey flows for an area of 84.2 ha from which only 10.7 ha accounts for the BSUEA lands. Similarly, culvert BDR-C7 was found to convey flows for an area of 12.6 ha, which is predominately from the BSUEA lands excluding a small 1.5 ha catchment along Barnsdale Road.

Given the hydraulic conductivity of the native soils, the implementation of distributed infiltration for the first 22 mm of runoff would ensure that pre-development groundwater flows and drainage boundaries are preserved at each of the sub-catchments. Hence, incorporating an EES would allow for the hydrological regime to be maintained at each of the municipal drains for frequent events up to 22 mm. Under events in excess of 22 mm, the recommended servicing strategy presented herein will redirect flow from the municipal drains to the Jock River (via the Greenbank Road trunk storm sewer). Hence, the overall area to either Municipal Drain will be slightly reduced as depicted in Figure 5-8.

Table 5-14 summarizes the simulated flows under pre- and post-development conditions for flows to the Thomas Baxter Municipal Drain and boundary culvert BDR-C7.

Table 5-14: Hydrological Simulation Results at Culvert Locations (12 hour - SCS Type II Storm)

Culvert ID	Flow (m^3/s) at culvert location for return period (recurrence in years)					
	1:2	1:5	1:10	1:25	1:50	1:100

Plot Date: February 23, 2018 11:10:01 AM

The simulated flows to Mud Creek under pre and post conditions (Table 5-14) show that there is a reduction in flows to the Thomas Baxter drain of around 0.1 m³/s in larger events and negligible reductions in flow in the frequent events. There is a greater reduction in flows draining towards the Municipal Drain through culvert BDR-C7.

5.11 Storm Servicing Evaluation

As presented above in this section, high level storm and stormwater management servicing was developed such that:

- Sizing of the storm sewer system meets or exceeds the minimum level of service of the OSDG;
- A minimum 300 mm freeboard is provided along the minor system with the exception of a few locations within the Mattamy Lands East;
- A major overland flow route is provided throughout the BSUEA lands safely convey major overland flow to the end-of-pipe facilities;
- Major overland flow is not conveyed across New Greenbank Road; and
- Major overland flow depths less than 350 mm are provided within the BSUEA lands.

The minor and major systems presented herein have been evaluated based on a series of criteria and summarized in Table 5-15.

Table 5-15: Storm Servicing Evaluation

Issue	Aspects	Advantages
Geotechnical Issues and Construction Risks	Potential for poor soils/rock/elevated groundwater table etc.	There is potential for the storm sewers to be close to the water table in the south east corner of the study area
Infrastructure Requirements	Extent of works required	Works are contained to those within the BSUEA
Phasing and Scheduling	Integration with development phasing	SWMFs will be required to be installed first
Property Acquisition / Land Use	Ease of property acquisition / compatibility with demonstration plan	Servicing is contained within proposed corridors and servicing parcels
System Flexibility	Ability to adapt to changes in demonstration plan	Sewers can adapt to ROW corridor changes. SWMFs required at low points
Displacement of existing land uses	Effects in removal of existing communities	All work within BSUEA
Disruption to existing land uses	Extent of works affecting existing communities	All work within BSUEA

Issue	Aspects	Advantages
Consistency with City Infrastructure	Compatibility with the OSDG and IMP	Adheres to local and provincial design guidelines
Impact on Significant Natural Features	Loss of natural areas due to servicing	Adheres to land use and demonstration plans
Impact on Aquatic Systems	Potential impact of water quality in receiving watercourses	Achieves required water quality standards
Impact on Surface Water and Groundwater	Minimization of works in waterbodies or in the groundwater table	May extend into the groundwater table in the south east of the site
Impact on esker	Preservation of pre-infiltration levels and achievement of distributed infiltration	The EES is the preferred servicing alternative to minimize the impact on the esker
Effects on Urban Green Space, Open Space and Vegetation	Disruption or loss of green space or trees due to servicing	Adheres to land use and demonstration plans
Efficiency of Proposed Infrastructure	Use of existing or combined corridors	Services are contained within combined corridors
Efficiency with Existing Infrastructure	Use of existing infrastructure or capacity	Utilizes residual capacity in existing infrastructure
Issue	**Aspects**	**Disadvantages**
Operational Impacts	Extent of maintenance intensive infrastructure	The use of the EES will increase maintenance. However, this has been limited in the design
System Reliability	Level of redundancy within system	EES may become clogged if not maintained, no direct overflow watercourse
Capital Costs	Initial Construction Cost	Increased capital cost of using EES compared to conventional sewers
Operating Costs	Ongoing operation and maintenance requirements	Increased maintenance of using EES compared to conventional sewers

5.12 Storm Summary and Recommendations

This section of the MSS has presented two (2) storm servicing options, one including a conventional storm system while an alternate servicing solution was developed incorporating an EES. Both servicing options were reviewed and their performance analyzed against the OSDG and other provincial guidelines. The conceptual design outlined above was found to fulfill the following:

- Achieves the prescribed flow rate along the Greenbank Road trunk storm sewer tributary to the Corrigan Pond (refer to Figure 5-5 and Figure 5-6 for peak flow comparisons);
- Achieves 300 mm freeboard across the BSUEA;
- Achieves flow depths of 350 mm along the major system of the BSUEA; and,
- Achieves infiltration levels, under the EES, comparable to existing levels. It is recommended that the analysis be refined at detailed design. Under the conventional system, the target to achieve distributed infiltration and preserve pre-infiltration levels is met.

It is recommended that storm servicing in the BSUEA be carried out using the EES on local roads and conventional storm sewers equipped with downstream HDS along collector and arterial roads. This recommended servicing strategy would fulfill; i) the enhanced water quality protection level, ii) achieve distributed infiltration and preserve pre-infiltration levels, iii) meet the prescribed peak flow rates prior to discharge into the Greenbank Road trunk sewer system.

In addition, it is recommended that the EES be approved for the initial phase of the development for both Minto and Mattamy to assess operation of the system. Consequently, it is recommended that the performance of the EES be assessed via flow monitoring as part of the initial phase of both builders (Minto and Mattamy) (Section 5.5.1.8). The extent and details of flow monitoring should be discussed with the City as part of the design stage of the initial phase of both builders (Minto and Mattamy). Should the flow monitoring identify deficiencies with the EES then storm servicing with infiltration galleries can be further investigated for implementation in Phase 2.

5.12.1 Stormwater Management

The overall approach to stormwater management is to combine the EES with the conventional storm system to ensure that the pre-infiltration levels are preserved. Calculations have revealed that the EES along local roads are sufficient in meeting MOE's enhanced protection level; however, a HDS would be required along collectors and arterials to meet the 80% TSS removal. Since quality control with the EES is provided along the ROWs, the end-of-pipe facilities abutting Greenbank Road would be dry ponds.

5.12.2 Storm Sewer Design

The proposed storm sewers within the BSUEA are designed to accommodate the 1:5 year capture rate under free flow conditions. The existing Quinn's Pointe storm sewer system can accommodate the 1:2 year peak flows from the BSUEA (Minto Lands) without any surcharge.

6.0 Wastewater Servicing

6.1 Background

The wastewater collection system for the BSUEA has been designed to convey wastewater to existing or planned gravity sanitary sewers in the BSC, which all eventually outlet to the Greenbank Road 900 mm diameter trunk sanitary sewer. The Greenbank Road trunk sanitary sewer ultimately discharges to the South Nepean Collector (SNC) and to the West Rideau Collector (WRC) which, in turn, outlets to the Robert O. Pickard Environmental Centre (ROPEC) where wastewater is processed and treated prior to discharge into the Ottawa River.

The existing BSC is currently serviced by existing trunk sanitary sewers located along Greenbank Road, Cambrian Road and River Mist Road, as shown on Figure 6-1. There are also trunk sanitary sewers that have yet to be constructed in the BSC, in accordance with the Draft 2014 BSMSSA. These planned sewers are located along the future Cambrian Road extension, New Greenbank Road, and the Future Collector Road located west of New Greenbank Road, as shown on Figure 6-1.

The wastewater servicing strategy for the BSUEA was developed to respect the integrity of the existing downstream system in regard to the known minimum residual capacities in the downstream trunk sanitary sewers. These critical residual capacities are summarized in Table 6-1 in terms of the three main trunk sewers in the BSC.

Table 6-1: Critical Residual Capacity in Existing Trunk Sanitary Sewers

Existing Trunk Sanitary Sewer	Limiting Pipe Reach	Residual Capacity
Cambrian Road	MH 13A to MH15A	51.4 L/s
River Mist Road	MH 102A to MH 17A	14.4 L/s
Greenbank Road	MH 45 to MH 435A	295.4 L/s

Section B7.1.1 of the Existing Conditions Report (Appendix B) should be reviewed for additional information regarding the existing and planned trunk sanitary sewers in the BSC.

6.2 Wastewater System Servicing

6.2.1 Design Criteria

Trunk sanitary sewers servicing the BSUEA were designed in accordance with the following criteria:

- Residential average flow rate 280 L/capita/day
- Commercial/Institutional average flow rate 28,000 L/ha/day
- Residential peaking factor Harmon formula

DRAWING NO.:	FIGURE 6-1

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\GIS\26610 C ExStmWatrInfra.dwg

PLOT DATE: September 12, 2017 9:07:53 AM

- Commercial/Institutional peaking factor 1.5[2]
- Infiltration allowance 0.33 L/s/ha
- Manning roughness coefficient 0.013
- Minimum velocity 0.6 m/s
- Maximum velocity 3.0 m/s

It is understood that the majority of the aforementioned design criteria deviate from the City of Ottawa 2012 Design Guidelines. However, it was confirmed by the City via email on December 6, 2017 (copy attached in Appendix J) that these revised criteria shall be applied to the design of the BSUEA MSS wastewater sewer system and to the existing downstream systems. In recent discussions with City staff, the MSS design team was advised that the City intends issuing these revised criteria as part of a forthcoming Technical Bulletin expected for early 2018.

6.2.2 Wastewater Flows

Theoretical residential wastewater peak flows generated in the BSUEA were calculated based on population forecasts obtained using the projected number of residential units in the BSUEA and corresponding population densities prescribed in the 2012 Design Guidelines. Total residential units counts were adopted from the BSUEA CDP for the Minto and Mattamy lands. As the unit values reported in the CDP document were expressed in terms of net area (36 units per net ha), an equivalent density of 63.9 persons/gross ha was used in order to calculate wastewater flows and size the sanitary sewers.

Table 6-2: Residential Densities

Residential Type	Number of Units	Population per Unit[3]
Detached	660 units	3.4
Multiple-Attached	420 units	2.7
Apartments (or similar density)	120 units	1.8
	1200 units	

Based on the land uses presented on the Demonstration Plan (Figure 4-2), theoretical peak wastewater flows for the BSUEA were calculated and are summarized in Table 6-3 below. To estimate the total amount of housing and ICI lands for the Aggregate Extraction Areas, the same ratios of roads, ICI and residential housing land uses as those used for the Minto and Mattamy lands, and outlined in the CDP, were assumed (park and ride was excluded). The Minto area/unit ratios were then applied to the residential lands portion of the Aggregate Extraction Areas to estimate the total number of units. The Park and Ride block

[2] *ICI Peak Factor = 1.5 when ICI contributing area >20%, 1.0 if ICI in contributing area is <20%.
[3] Densities are in accordance with Section 4.3 of the 2012 Design Guidelines.

was assumed to have 4 washbasins that deliver 375 L/d and four (4) water closets that generate 150 L/hr for 10 hr/day resulting in a total flow of 7500 L/day.

Table 6-3: Land Use and Theoretical Wastewater Flows

Total		**121.0**		**5746**	**26.22**		**40.0**	**106.7**

Based on the land uses presented on the Demonstration Plan (Figure 4-2), the BSUEA would generate a peak wastewater flow of approximately 106.7 L/s.

6.3 Wastewater Collection System Strategy

6.3.1 Proposed Sewer System Layout and Sizing

A trunk sanitary sewer system layout was developed based on the ROW corridors identified on the BSUEA Demonstration Plan for the purposes of demonstrating the feasibility of providing wastewater servicing for the BSUEA lands, refer to the Key Servicing Plans. Proposed trunk sanitary sewers were sized based on the aforementioned design criteria and the drainage areas depicted on the Master Sanitary Drainage Area Drawing MSAN, refer to the BSUEA Sanitary Sewer Design Sheet (Appendix J) for detailed calculations. Final configuration and sizing of the wastewater collection system will be confirmed at detailed design of each subdivision stage. At such time, refinements may be implemented.

The proposed BSUEA trunk sanitary sewers will discharge to existing/planned sanitary sewers at the following six (6) locations, as shown on Figure 6-2:

1. The Future Collector Road
2. New Greenbank Road
3. Flameflower Street

6.3.1.1 Future Collector Road (west of new Greenbank Road) Outlet

The Drummond Aggregate Extraction Area will be serviced by a connection (at MA11) to the planned trunk sanitary sewer on the Future Collector Road. This planned trunk sanitary sewer will outlet to the planned Cambrian Road trunk sanitary sewer, located west of New Greenbank Road, as identified in the 2014 BSMSSA. The proposed BSUEA sanitary sewer system within the Drummond property was conceptually sized to be 200 mm in diameter with a slope of 0.35% assuming that the development of the Aggregate Extraction Area would generally consists of a residential land usage. Although a demonstration plan is not currently available for this area, a high level trunk sanitary sewer layout was developed for the property.

Per the Draft 2014 BSMSSA, the specified obvert elevation of 95.00 m at maintenance hole MA11, which is located at the northern limit of the BSUEA, is proposed to be respected. Based on this outlet obvert elevation and based on a high level sewer layout concept, which would cross above the future storm sewer system, an upstream obvert elevation of 99.20 m would result at MH 593 within the southeastern corner of the Drummond Aggregate Extraction Area. As discussed in Section 5.7.5, the existing Drummond Aggregate Extraction Area must be reinstated to a minimum elevation of 104.0 m. Allowing for a 3.0m cover over the sanitary sewer system, would require a reinstated elevation of approximately 102.2m, which would still be within the minimum required reinstatement elevation of 104.0 m.

6.3.1.2 New Greenbank Road Outlet

The Brazeau Aggregate Extraction Area will be serviced by a connection (at MA14) to the planned trunk sanitary sewer on the New Greenbank Road. This planned trunk sanitary sewer will outlet to the existing Cambrian Road trunk sanitary sewer, located east of New Greenbank Road, as identified in the 2014 BSMSSA.

The proposed BSUEA sanitary sewer system within the Brazeau property was conceptually sized to be 250 mm in diameter with a slope of 0.24% assuming that the development of the Aggregate Extraction Area would generally consists of a residential land usage. Although a demonstration plan is not currently available for this area, a high level sanitary sewer layout was developed for the property.

Per the Draft 2014 BSMSSA, the specified obvert elevation of 96.10 m at maintenance hole MA14, which is located at the northern limit of the BSUEA, is proposed to be respected. Based on this outlet obvert elevation and based on the high level sewer layout developed for the site, an upstream sanitary sewer obvert elevation of 98.55 m would result at MH 585 within the southwest corner of the Brazeau Aggregate Extraction Area.

As discussed in Section 5.7.5, the existing Brazeau Aggregate Extraction Area must be reinstated to a minimum elevation of 97.0 m. However, when accounting for a 3.0 m cover over the sanitary sewers in the westerly half of the property, a minimum reinstated elevation of approximately 101.55 m would be required. Similarly, when accounting for a 3.0 m cover over the storm sewer system (as

described in Section 5.7.5) in the easterly half of the site, a minimum reinstated elevation of approximately 102.5 m would be required. Per the available existing topography of the Brazeau lands, the lowest topography appears to be approximately 98.0 m. Consequently, to service the Brazeau Aggregate Extraction Area with gravity sewers, with an allowable 3.0 m cover, it is anticipated that some areas may require as much as 4.5 m of fill.

Wastewater generated by Mattamy Lands West, will outlet to the planned 250 mm diameter sanitary sewer on New Greenbank Road at MA14. The planned New Greenbank Road sanitary sewer will discharge to the Cambrian Road trunk sanitary sewer as per the Draft 2014 BSMSSA.

A southerly extension of the 250 mm diameter New Greenbank Road trunk sanitary sewer will be required to service the proposed BSUEA tributary area. A new trunk sanitary sewer segment is proposed from MH 900 to MA14, as shown on the Key Servicing Plan. This proposed sewer segment is much shallower than the planned portion of the trunk downstream of MA 14 where cover depth is in the range of 6.9 m. The proposed sewer segment will have a proposed cover depth of 7.43 m.

6.3.1.3 Flameflower Street Outlet

The 2 ha commercial block located west of New Greenbank Road as well as a 2 ha portion of Mattamy Lands East will be serviced by a connection to the existing 200 mm diameter sanitary sewer located on Fameflower Street at MH EX 217. The existing Fameflower street sewer conveys wastewater to the Dundonald Drive sanitary sewer which ultimately outlets to the existing River Mist Road trunk sanitary sewer.

A 200 mm diameter local sanitary sewer is proposed to service the residential and commercial development. A drop maintenance hole is expected at MH 920 due to the relatively high elevation of the commercial block and New Greenbank Road compared to the residential development, as shown on the Master Grading Plan, Drawing MG1.

6.3.1.4 Alex Polowin Avenue Outlet

Wastewater generated by 5 ha of Mattamy Lands East will be conveyed to the existing 200 mm diameter sanitary sewer on Alex Polowin via two (2) connection points: MH EX153 and MH EX158. The existing Alex Polowin sewer will convey wastewater northerly to the Des Soldats Reindeau Street sanitary sewer which ultimately outlets to the River Mist Road trunk sanitary sewer.

Two (2) parallel local 200 mm diameter sanitary sewers are proposed to convey wastewater generated in the BSUEA tributary area to the proposed outlet locations.

6.3.1.5 Kilbirnie Drive Outlet

Residential development and the school fronting the Kilbirnie Drive extension as well as the northern portions of Alex Polowin (south of Kilbirnie) and Street 1, in the Minto Lands, will be serviced by a connection at MH 10 to the existing 200 mm

diameter sanitary sewer along Kilbirnie Drive. The existing Kilbirnie Drive local sanitary sewer conveys wastewater easterly to the River Mist Road trunk sewer.

The Kilbirnie Drive outlet is proposed as a result of the naturally low-lying area at the intersection of Kilbirnie Drive and Street 1 relative to the rest of the Minto Lands. If this naturally low-lying area were to be serviced via a sanitary sewer network to the south, then the sanitary sewer would have to be excessively deep or extensive amounts of fill would be required.

6.3.1.6 Greenbank Road Outlet

Wastewater generated by the majority of the Minto Lands (i.e., 59.86 ha) will outlet to the existing 600 mm diameter Greenbank Road trunk sanitary sewer at existing MH 120. This includes some wastewater generated in the existing Quinn's Pointe development (1.14 ha) which will be redirected away from the River Mist Road trunk sanitary sewer to the Greenbank Road trunk sanitary sewer via the proposed BSUEA sanitary sewers. Wastewater conveyed by sewer reaches on Alex Polowin (MH EX13 - EX14) and Russet Terrace (MH EX14 - EX5) will be conveyed in a southerly direction along a new sanitary sewer on River Mist Road. The purpose of this diversion is to increase the available capacity in the River Mist Road trunk sanitary sewer in order to accommodate additional BSUEA peak flows.

Wastewater generated in the BSUEA will be conveyed to the Greenbank Road trunk via two main trunk sanitary sewers: i) along the East-west Collector, and ii) along the southern limit of the BSUEA and Barnsdale Road. As shown on the Master Sanitary Drainage Area Plan, generally most Minto Lands to the north of the East-west Collector will outlet to the East-west Collector trunk while Minto Lands to the south of the East-west Collector will outlet to the trunk sewer located along the southern limit of the BSUEA and Barnsdale Road. Both trunk sanitary sewers range in size between 200 mm and 450 mm in diameter.

An extension of the existing Greenbank Road trunk sanitary sewer is required to provide the necessary connections to the proposed BSUEA trunks. A 525 mm diameter trunk will convey wastewater along Greenbank Road from Barnsdale Road to the East-West Collector (MH 538-119) and a 600 mm diameter trunk sewer will convey wastewater from the East-West Collector to the existing sewer at MH EX120.

6.4 Impact of BSUEA Flows on Downstream System

Sanitary sewer design sheets were compiled for the BSC trunk wastewater collection system to verify the impact of the additional flow generated by the BSUEA on the existing downstream sewer system (refer to Appendix J). With the addition of the BSUEA lands, the calculated theoretical peak wastewater flows were found to be within the available residual capacities of the existing downstream sanitary sewers. Consequently, no further infrastructure improvements are required along the existing downstream system in the BSC. Table 6-4 provides a summary of the impact of the BSUEA on the available residual capacities in terms of the three main existing trunk sanitary sewers in the BSC.

It is noted that the residual capacity in the River Mist Road trunk sanitary sewer has in fact increased with the addition of the BSUEA peak flows. This is the result of adding a relatively small tributary area while reducing the average daily residential flow from 350 L/cap to 280 L/cap combined with diverting some existing drainage areas, located in Quinn's Pointe, away from the outlet.

Table 6-4: Residual Capacity Comparison in the BSC Trunk Sanitary Sewers

Existing Trunk Sanitary Sewer	Limiting Pipe reach	Current Minimum Residual Capacity	Proposed BSUEA Tributary Lands	Proposed BSUEA Tributary Area	Revised Minimum Residual Capacity with inclusion of BSUEA Peak Flow
Cambrian Road	MH 13A to MH15A	51.4 L/s	Drummond, Brazeau, Mattamy West (Residential only)	48 ha	52.9 L/s
River Mist Road	MH 102A to MH 17A	14.4 L/s	Mattamy East, Mattamy West (Commercial only), Northwest corner of Minto	12 ha	30.5 L/s
River Mist Road	MH 1 to MH 163	5.58 L/s	Minto	5 ha	4.63 L/s
Greenbank Road	MH 45 to MH 435A	295.4 L/s	Minto	60 ha	283.2 L/s

With the addition of the BSUEA lands, a total theoretical peak wastewater flow of 403.7 L/s was calculated at the most downstream maintenance hole in the BSC (MH 501A on Greenbank Road), as indicated in the Sanitary Sewer Design Sheet in Appendix J. This calculated theoretical peak flow is less than the 590 L/s allocated for all of the BSC in Stantec's City-wide 2013 Wastewater Collection System Assessment. In this assessment, Stantec created a hydrodynamic model of trunk sanitary sewers (450 mm in diameter and greater) which demonstrated that the existing downstream trunk system could accommodate the theoretical flow of 590 L/s generated by the BSC with no risk of surcharging or basement flooding. Consequently, Stantec concluded that system upgrades were not required to accommodate the anticipated growth in the BSC. Since the Stantec assessment considered a peak flow that was 186 L/s greater than that calculated for the BSC and the BSUEA combined, it is understood that the existing trunk sanitary sewers located downstream of the BSC can accommodate the additional flows generated by the BSUEA.

6.5 Detailed Wastewater Servicing Evaluation

The wastewater collection system presented on Drawing DSAN and associated design sheets has been conceptually sized to comply with the City's revised December 6, 2017 design criteria and to respect the integrity of the existing systems. The proposed wastewater collection system has been evaluated based on a series of criteria and summarized in Table 6-5.

Table 6-5: Wastewater Servicing Evaluation

Issue	Aspects	Advantages
Geotechnical Issues and Construction Risks	Potential for poor soils/rock/elevated groundwater table, etc.	There is potential for the wastewater system to be close to the water table in the south east corner of the study area
Infrastructure Requirements	Extent of works required	Works are required outside the BSUEA but are limited to upgrading of planned infrastructure
Operational Impacts	Extent of maintenance intensive infrastructure	Conventional wastewater system with no additional pumps or treatment facilities
Phasing and Scheduling	Integration with development phasing	Multiple points of connection allow flexibility with phasing.
Property Acquisition / Land Use	Ease of property acquisition / compatibility with demonstration plan	Servicing is contained within proposed ROW corridors and servicing parcels, except an easement parallel to Barnsdale Road.
System Reliability	Level of redundancy within system	Overflow is provided to a SWMF
System Flexibility	Ability to adapt to changes in demonstration plan	Wastewater collection system can adapt to ROW corridor changes. However, connection points with the existing infrastructure are fixed
Displacement of existing land uses	Effects in removal of existing communities	All work within BSUEA
Disruption to existing land uses	Extent of works affecting existing communities	All work within BSUEA
Consistency with City Infrastructure	Compatibility with the OSDG and IMP	Adheres to local and provincial design guidelines

Issue	Aspects	Advantages
Impact on Significant Natural Features	Loss of natural areas due to servicing	Adheres to land use and demonstration plans
Impact on Aquatic Systems	Potential impact of water quality in receiving watercourses	No receiving watercourses or watercourses affected during construction
Impact on Surface Water and Groundwater	Minimization of works in waterbodies or in the groundwater table	No watercourses affected during construction. Groundwater in south-east corner may be affected depending on depths
Effects on Urban Green Space, Open Space and Vegetation	Disruption or loss of green space or trees due to servicing	Adheres to land use and demonstration plans
Efficiency of Proposed Infrastructure	Use of existing or combined corridors	Services are contained within combined corridors
Efficiency with Existing Infrastructure	Use of existing infrastructure or capacity	Utilizes residual capacity in existing infrastructure
Capital Costs	Initial Construction Cost	Standard sewer design
Operating Costs	Ongoing operation and maintenance requirements	Gravity sewers only with no pumping or pressure lines

6.6 Wastewater Summary and Recommendations

Wastewater servicing for the BSEUA will be provided by a network of gravity trunk sanitary sewers ranging between 200 mm and 600 mm in diameter, as shown on Drawing MSAN. The trunk sanitary sewer network will outlet to existing and planned sanitary sewers at six (6) locations: i) the Future Collector Road, ii) New Greenbank Road, iii) Fameflower Street, iv) Alex Polowin Avenue, v) Kilbirnie Drive, and vi) Greenbank Road. Based on the land uses identified on the Demonstration Plan, the design criteria summarized in Section 6.2.1 and the drainage areas delineated on Drawing MSAN, the existing downstream sanitary sewers at those six (6) locations can accommodate the additional peak flow generated by the BSUEA, as demonstrated in the Sanitary Sewer Design Sheets presented in Appendix J. Final configuration and sizing of the sanitary sewer system may be refined at detailed design of each subdivision stage.

7.0 Water Distribution

7.1 Background

A water supply assessment was conducted for the BSUEA to investigate whether the extension of existing watermains would provide potable water that meets the hydraulic objectives described in Section 4.2 of the OSDG (water distribution).

A review of the existing and future planned watermains was carried out as part of the Existing Condition Report (JLR, 2017). Figure 7-1 depicts the existing and planned watermains along the boundary of the BSUEA lands. This review has shown that the current urban development to the east of the study area is served by the municipal distribution system, which draws its water from the Ottawa River at both the Britannia and Lemieux Water Purification Plants. From those plants, potable water is distributed via a series of water booster stations. The City water distribution system is planned based on achieving the following design objectives:

- Quantity: sufficient water at sufficient pressure (Section 4.2 of the Ottawa Design Guidelines for water distribution, July 2010);
- Quality: safe drinking water to the required standards (Section 4.1 of the Ottawa Design Guidelines for water distribution);
- Reliability: to ensure water supply under emergency conditions; and,
- Effectiveness and affordability: to reduce lifecycle costs being sustainable in the long term.

The existing BSC is part of the City's Pressure Zone BARR, which is fed from Pressure Zone 2W via the Woodroffe Avenue 1200 mm diameter transmission watermain and the Fallowfield Road 762 mm diameter transmission watermain. The Barrhaven Reservoir located off Fallowfield Road, acts as balancing storage for Zone 2W and feeds the Barrhaven Pumping Station (BPS), which boosts water to the Pressure Zone BARR.

Three (3) feedermains service the BSC from the Barrhaven reservoir, which are as follows:

- a 406 mm main along Greenbank Road;
- a 406 mm main along Cambrian Road; and,
- a 305 mm feeder main along River Mist Road.

Three (3) additional feedermains are planned as the BSC expands which in turn will trigger increases in water demand. These feedermains are as follows:

- a 305 mm main along New Greenbank Road;
- a 406 mm main on Cambrian Road; and,
- a 305 mm main on the future Collector Road between New Greenbank Road and Borrisokane Road.

PLOT DATE: September 12, 2017 9:08:20 AM

In 2016, Stantec was tasked to carry out a potable water analysis to determine whether the supply characteristics of the existing and planned watermains in the BSC would be sufficient to accommodate the projected demands of the BSUEA under both existing and build-out conditions. The Technical Memorandum entitled "Barrhaven MSS Addendum – Revised Potable Water and Sanitary Servicing Analysis for the Barrhaven South Urban Expansion Area, October 19, 2016" summarized the findings of the analysis which is included in Appendix I. Initially, the potable water analysis was carried out assuming that both the Brazeau and Drummond aggregate extraction areas would be developed as commercial/employment usages; however, it has since been considered as having residential usage. It should also be noted that ICI demands from the remaining parts of the BSUEA lands was not incorporated by Stantec in their potable water analysis. The modelling presented herein has incorporated ICI demands.

Water demands were calculated based on zone/system level criteria as the overall population in the BSUEA exceeded 3,000. The calculated water demand was distributed over four (4) nodes along the existing backbone of the system (i.e., along an existing 300 mm diameter watermain within Quinn's Pointe) as shown on Stantec's Figure 4 (Appendix I). The analysis first confirmed that the BSUEA does not require any off-site watermains to support its development. The analysis also showed that, during peak hour demand conditions, pressures are expected to meet the prescribed pressure of 40 psi (275 kPa) within the existing Quinn's Pointe. However, areas of higher topography along the existing backbone as depicted on Stantec's Figure 7 will have pressures of 40 psi (275 kPa) or less. The analysis concluded that the performance of the local watermains within the existing areas met the prescribed pressures and that the proposed watermains within the BSUEA be evaluated as part of the MSS.

7.2 Water Servicing Criteria

7.2.1 Design Criteria

The water supply servicing for the BSUEA complies with the Ottawa Design Guidelines for Water Distribution (July 2010), which require that the water supply system be designed to satisfy the greater of either of the following criteria:

- Maximum day demand plus fire flow; or,
- Maximum hourly demand (peak hour demand)

Section 4.2.2 of the Design Guidelines for Water Distribution requires that all new development additions to the public water distribution system be designed such that the minimum and maximum water pressures, as well as flow rates, conform to the following:

- Under maximum hourly demand conditions (peak hour), the pressures are not less than 276 kPa (40 psi);
- During periods of maximum day and fire flow demand, the residual pressure at any point in the distribution system shall not be less than 140 kPa (20 psi);
- In accordance with the Ontario Building Code in areas that may be occupied, the static pressure at any fixture shall not exceed 552 kPa (80 psi);
- The maximum pressure at any point in the distribution system in unoccupied areas shall not exceed 689 kPa (100 psi); and,

- Feedermains, which have been provided primarily for the purpose of redundancy, shall meet, at a minimum, the basic day plus fire flow demand.

In addition to the above targets, servicing should be carried out to minimize dead-ends.

7.2.2 Domestic Water Demand

The water demands presented in this section are based on the same unit and population estimates as per the wastewater servicing flows described in Section 6.2.1, which reflects the CDP unit count. The zone/system level criteria for water demands are based on land use type and are in Table 7-1 below. The water demand criteria are consistent with those used in Stantec's Revised Potable Water Servicing Analysis (October 19, 2016). Calculations are summarized below.

Basic Day (BSDY) demands are calculated from the system level water demands for residential, commercial and institutional land uses. Maximum Day (MXDY) demands are calculated by adding an Outdoor Water Demand (OWD) also shown in Table 7-1 below. Peak hour demands result from applying the 72-hour diurnal patterns developed by the City to each type of MXDY demand. The 72-hour diurnal patterns are unique to each type of land use to reflect the different use patterns. The maximum hourly demand observed within the 72-hour patterns is the Peak Hour (PKHR) demand.

The review of the Demonstration Plan (Figure 4-2) has revealed that the number of units and associated densities will result in an overall population that will exceed 3,000. As a result, the water supply analysis presented herein is to be conducted using system level water demands as developed by the City. These system level demands are summarized in Table 7-2.

Table 7-1: Theoretical Water Consumption Rate

Land Use Type	Consumption Rate	Units
Single Family Residential	180	L/cap/day
Multi-unit Residential (Townhouse / Back to Back)	198	
Apartment Residential	219	
Commercial	50,000	L/ha/day
Institutional	50,000	
Outside Water Demand	1,049	L/SFH/day

The above system level demands were applied to each of the blocks depicted on the Demonstration Plan. As previously noted, the Brazeau and Drummond aggregate properties have now been accounted as residential usage. It was assumed that residential densities for both properties would be consistent with those for the BSUEA. Based on this exercise, overall water demands of 18.66 L/s and 31.48 L/s were calculated for the basic day (BSDY) and maximum day

(MXDY), respectively. It should be noted that MXDY of 31.48 L/s includes an outside water usage of 10.15 L/s.

Table 7-2: Estimated Water Demands

Land Use	Area (ha)	Units	Pop.	ADD SFH[4]	ADD MLT[5]	ADD APT[6]	ADD COM[7]	ADD INS[8]	Total BSDY	OWD[9]	Total MXDY

7.2.3 Watermain Sizing and Roughness

The overall watermain layout for the BSUEA is shown on Drawing MWM. Watermain roughness coefficients were determined using the friction factors presented in Section 4.2.12 of the Design Guidelines and summarized in Table 7-3 below. The internal pipe diameters were modelled based on Section 4.3.5 of the Design Guidelines, as summarized in Table 7-4 below.

Table 7-3: Watermain Roughness Coefficients

Watermain Diameter	C-Factor
150 mm	100
200 to 250 mm	110
300 to 600 mm	120
Over 600 mm	130

Table 7-4: PVC Watermain Internal Diameters

Nominal Diameter	Inside Diameter
150 mm	155 mm
200 mm	204 mm
300 mm	297 mm
400 mm	393 mm

7.2.4 Fire Flow

The City standard in regard to fire protection is the Fire Underwriters Survey and Technical Bulletin ISDTB-2014-02. To evaluate the proposed water distribution system, a fire flow of 13,000 L/min (217 L/s) was used in this system level analysis in accordance with the recommendations of the 2013 Water Master Plan.

7.3 Water Servicing Design

7.3.1 Watermain Servicing and Alignments

7.3.1.1 Minto Lands

A single water main loop is proposed as the main backbone within the BSUEA. This backbone will span through the Minto Lands, along the New Greenbank Road and the East-West Collector. This feedermain would then connect to the existing 400 mm feedermain on Greenbank Road and to the planned feedermain for New Greenbank Road to the north. To supplement this backbone spine, it is also proposed to make connections to the above-noted backbone via the River Mist and Kilbirnie Drive 300 mm diameter watermains. Internal system looping via 200 mm diameter watermains will also be provided.

7.3.1.2 Mattamy Lands East

Mattamy Lands East will be serviced through the water feedermains in the Half Moon Bay South subdivision via Fameflower Street.

7.3.1.3 Mattamy Lands West

Mattamy Lands West will be serviced via watermain extensions from the Half Moon Bay West subdivision.

7.3.1.4 Aggregate Extraction Areas

Given the phasing for the Aggregate Extraction Areas, water servicing for both properties will be achieved via watermain extensions off of the eastern portion of the BSUEA. System looping will be required within both properties with feedermain connections to the; i) future 300 mm diameter feedermain along New Greenbank Road, ii) future 300 mm diameter feedermain along the future North Collector, and iii) connection to the Kilbirnie Drive extension.

7.3.2 Water Modelling and Boundary Conditions

At the onset of this Study, the City provided an extract of the City wide water model that covered part of the Pressure Zone 3C which includes the BSUEA study area. The model's extract - with boundary conditions at the three (3) 2031 connection points with the wider City system (Table 7-5) - can be used to assess the performance of the proposed water distribution under existing (2016) and build-out (2031) conditions of the BSUEA lands. The boundary locations are shown below in Figure 7-1.

The existing (2016) supply characteristics of the distribution system have been simulated via two (2) static reservoirs; one is located at the Longfields Drive/Jockvale Road intersection, while the second is located near the Jockvale Road/Greenbank Road intersection. Under the build-out condition (2031), a third reservoir is being used in the simulation to reflect the additional supply that will occur from the new connector link along Regional Road 19 (River Road) that will be constructed as per the Infrastructure Master Plan. This third connection will

improve system reliability and supply for both Manotick Village and the BSC. This additional boundary condition is included in the 2031 build out version of the model.

The model extract was revised to include the backbone watermains shown on Drawing MWM along with the calculated demands (Table 7-2) distributed along various nodes within the study area. The model is included in with the data files in Appendix N.

Table 7-5: Boundary Condition Head Elevations

Scenario	Node Location	Basic Day (m)	Peak Hour (m)	Max Day Plus Fire[10] (m)
2016	3236	146.8	143.0	145.0
2016	18595	146.7	141.0	143.0
2031	3236	146.7	141.8	144.2
2031	18595	146.6	140.0	143.0
2031	F_MWL3	146.1	135.4	140.3

7.3.1 Ground Elevations

Topography within the BSUEA falls when moving easterly towards Greenbank Road; elevations generally range between 112 m in the western portion to 99 m in the eastern portion of the study area. There are also a series of knolls south of the Brazeau property with elevations reaching 115 m. Figure 7-1 shows existing ground elevations as per the LiDAR data while Drawings MG1 and MG2 shows preliminary grades at key locations within the BSUEA.

7.3.2 Impact of Demonstration Plan versus Water Quality

The supply of safe drinking water to the end users is key for operators of water distribution systems. Section 4.1.2 of the City of Ottawa's Design Guidelines for water distribution system speaks about water stagnation due to poor configuration and dead ends as well as oversizing of watermains. The preferred Demonstration Plan was developed to minimize the occurrence of dead-ends. Furthermore, watermain servicing within multi-unit residential areas have been limited to 200 mm diameter in size as per the recommendations of Technical Bulletin ISDTB-2014-02. Trunk watermain layout, as described below in Section 7.3.1, was kept to extensions of existing watermains of nominal diameters of 300 mm and 400 mm to minimize water stagnation.

[10] Fire demand was applied at Node B_30318 within the BSUEA

Figure 7-2: Boundary Condition Locations

7.4 Water Servicing Analysis

7.4.1 Basic Day (BSDY) and Peak Hour (PKHR) Conditions

The proposed watermain servicing within the BSUEA lands is depicted on Drawing MWM. The backbone of the existing distribution system that consists of 300 mm and 400 mm diameter watermain has been extended in the BSUEA. As shown on Drawing MWM, a few local watermains (200 mm diameter) were added to the analysis in a critical area where centerline elevations exceed 106.0 m. The proposed backbone providing supply to the BSUEA includes the following watermains:

- 400 mm Greenbank Road Extension (from Existing at Knockaderry Crescent - Barnsdale Road);
- 300 mm East-West Collector (Greenbank Road - Western limit of CDP);
- 300 mm Kilbirnie Drive Extension (Alex Polowin Avenue - Park & Ride);
- 300 mm Future Collector Road Extension (Northern Limit of Drummond - Kilbirnie Drive Extension);
- 300 mm New Greenbank Road (Barnsdale Road - Northern limit of CDP); and
- 300 mm River Mist Road Extension (Northern CDP Limit - East-West Collector).

The water demands summarized in Table 7-2 were distributed in the model over nine (9) nodes of the BSUEA. A Model Schematic was prepared (Figure 7-4) that shows the centre line elevations and watermain sizing within the BSUEA.

7.4.1.1 Existing Condition (2016 Scenario)

The 2016 existing condition model obtained from the City was revised as follows:

i) proposed watermains identified on Drawing MWM were incorporated,

ii) water demands described in Table 7-2 were added to the system. Water demands were revised from those reported in the September 2017 MSS and now reflects residential usage for both Brazeau and Drummond aggregate extraction properties, and

iii) the supply characteristics of the system were set to the static elevations identified in Table 7-5 under the 2016 scenario.

The performance of the proposed distribution system was evaluated under domestic demand conditions; Figure 7-5 depicts the basic day (BSDY) simulation while Figure 7-6 depicts the minimum pressure encountered during the 72-hour peak hour (PKHR) condition. An additional figure was prepared (Figure 7-7) showing the average pressure during the 72-hour PKHR condition.

Plot Date: May 2, 2018 9:25:34 AM

The performance of the distribution system was evaluated under domestic demands for the existing condition (2016). Simulation results have shown the following:

- Under the BSDY simulation (Figure 7-5), pressures within the BSUEA will not exceed the maximum pressure criterion of 80 psi (552 kPa);
- Under the PKHR demand scenario, the minimum pressures during this 72-hour simulation (Figure 7-6) range between 32.6 psi (225 kPa) and 51.2 psi (353 kPa). In general, a number of nodes located west of New Greenbank Road will exhibit pressures below the minimum pressure criterion of 40 psi (276 kPa);
- Under the PKHR demand scenario, the average pressures during this 72-hour simulation (Figure 7-7) range between 40.4 psi (279 kPa) and 58.9 psi (406 kPa), thereby satisfying the minimum pressure constraint of 40 psi (276 kPa).

Although the minimum pressure constraint of 40 psi is not met during the minimum hour of the 72-hour PKHR simulation, it is met everywhere in the BSUEA during the average pressure of the 72-hour PKHR simulation. Hence, it is recommended that this deviation to the Guidelines be accepted.

7.4.1.2 Build-out Condition (2031 Scenario)

The 2031 build-out condition model obtained from the City was revised as follows:

- proposed watermains identified on Drawing MWM were incorporated;
- water demands identified in Table 7-2 were added to the system; and
- the supply characteristics of the system were set to the static elevations identified in Table 7-5 under the 2031 scenario.

The performance of the proposed distribution system was evaluated under domestic demands for the build-out conditions (2031). Simulation results have shown the following:

- Under the BSDY simulation (Figure 7-8), pressures within the BSUEA will not exceed the maximum pressure constraint of 80 psi (552 kPa);
- Under the PKHR demand scenario, the minimum pressures during this 72-hour simulation (Figure 7-9) range between 32.2 psi (222 kPa) and 50.7 psi (350 kPa). In general, a number of nodes located west of New Greenbank Road will exhibit pressures below the minimum pressure criterion of 40 psi (276 kPa);
- Under the PKHR demand scenario, the average pressures during this 72-hour simulation (Figure 7-10) range between 37.7 psi (260 kPa) and 56.2 psi (387 kPa). Specifically, there are four (4) nodes that do not satisfy the minimum pressure constraint of 40 psi (276 kPa). These nodes are located in the southwest quadrant of the Kilbirnie Drive extension and New Greenbank Road intersection.

Plot Date: May 2, 2018 10:08:42 AM

A further review of the PKHR simulation results was carried out for the southwestern quadrant noted above. The results for the 72-hour PKHR (average and minimum pressures) has showed that deficient nodes with pressures less than 40 psi (275 kPa) were solely due to topography and not related to excessive headlosses along the distribution system. Therefore, upsizing watermains in that quadrant to 300 mm was found not to increase the simulated pressure. The review of Drawings MG1 and MG2 has showed that proposed centerline elevations in that quadrant of the BSUEA range between 106.2 m to 111.0 m; pressures associated with low topography of 106.2 met the minimum pressure constraint under the PKHR (average) while topography of 111.0 m generated pressures below the minimum pressure constraint.

To minimize the inconvenience of low pressures during the occurrence of a peak hour demand (i.e., a few hours per year), mitigation measures such as oversized service laterals (25 mm) and oversize internal plumbing are recommended. To determine the extent of these mitigation measures, the simulated hydraulic grade line was used as well as the proposed centerline elevations to determine the varying pressure head in the southwest quadrant of New Greenbank Road/Street 2 intersection. Based on the simulated HGL of 137.5 m (average pressure during the 72-hour PKHR simulation), the pressure head was calculated for various centerline elevations. The findings of this analysis are summarized in Table 7-6.

Table 7-6: Pressure Head versus Centreline Elevation

Road Centreline Elevation (m)	Head Differential (m): based on HGL of 137.5 m	Pressure head (psi): based on HGL of 137.5 m
111.0	26.5	37.6
110.5	27.0	38.3
110.0	27.5	39.1
109.5	28.0	39.8
109.0	28.5	40.5
108.5	29.0	41.2
108.0	29.5	41.9
107.5	30.0	42.6
107.0	30.5	43.3
106.5	31.0	44.0

Based on the above calculated pressure heads during PKHR (i.e., 72-hour average pressure), servicing in areas with proposed centerline elevations greater to or equal to 109.0 m should incorporate mitigation measures (i.e., 25 mm service lateral and oversized internal plumbing) to reduce headlosses from the ROW watermain to each of the house fixtures. Figure 7-10 depicts an area that abuts the western perimeter of the Park and Ride facility where servicing of

residential units be completed with mitigation measures. The extent of this area should, however, be finalized pending the final grading plan and a more detailed analysis at detailed design. Although the minimum pressure constraint will not be achieved, the recommended measures are appropriate to reduce the inconvenience of low pressures. Hence, it is recommended that this deviation to the Guidelines be accepted.

7.4.2 Maximum Day plus Fire Flow Conditions

To ensure adequate fire protection, a maximum day demand was simultaneously simulated with a fire flow along the proposed watermains within the BSUEA. As per Section 7.2.4, a system level fire flow of 13,000 L/min (217 L/s) was used in this analysis with the static elevations reported in Table 7-5 under existing (2016) and build-out conditions (2031).

7.4.2.1 Existing Condition (2016 Scenario)

The watermain layout as depicted on Drawing MWM was found, in general, to be capable of delivering fire flows in excess of 13,000 L/min (217 L/s) within the BSUEA during a maximum day demand as shown on Figure 7-11. However, there are two (2) nodes located within the Mattamy Lands East that do not meet the system level fire flow of 13,000 L/min (217 L/s). Those nodes, located next to New Greenbank Road, have a fire flow availability that exceeds the cap fire flow of 10,000 L/min (167 L/s) as per Technical Bulletin ISDTB-2014-02; the two (2) nodes show fire flows of 190.3 L/s and 199.4 L/s. Given that fire flow at the boundary of the property of the Mattamy Lands East exceed 21,300 L/min (356 L/s), it is recommended that hydrant spacing within the Mattamy Lands East be developed by locating proposed hydrants closest to existing Half Moon Bay rather than New Greenbank Road. This servicing approach would increase fire flow availability within the Mattamy Lands East and potentially meet the system fire flow of 13,000 L/min (217 L/s). It is therefore recommended, that hydrant spacing be reviewed closely at detailed design of the Mattamy Lands East to maximize fire flow availability. It should also be noted that since the previous submission, the City has issued a Technical Bulletin (ISTB-2018-02) on water distribution, particularly in regard to hydrant capacity requirements and required fire flow (RFF). This Bulletin allows that the aggregate fire flow capacity of all contributing fire hydrants within 150 m of a building/structure be used against the RFF. Contributing hydrant flow should reflect those in Table 1 of Appendix I of the Technical Bulletin.

7.4.2.2 Build-out Condition (2031 Scenario)

The watermain layout as depicted on Drawing MWM was found, in general, to be capable of delivering fire flows in excess of 13,000 L/min (217 L/s) within the BSUEA during a maximum day demand as shown on Figure 7-12. However, there are two (2) nodes located within the Mattamy Lands East that do not meet the fire flow of 13,000 L/min (217 L/s). Those nodes, located next to New Greenbank Road, have a fire flow availability that exceeds the cap fire flow of 10,000 L/min (167 L/s) as per Technical Bulletin ISDTB-2014-02. Given that fire flow at the boundary of the property exceed 22,000 L/min (368 L/s), it is recommended that

hydrant spacing be carried out to locate proposed hydrants closest to existing Half Moon Bay rather than New Greenbank Road. This servicing approach would increase fire flow availability within the Mattamy Lands East. It is therefore recommended that hydrant spacing be reviewed closely at detailed design to maximize fire flow availability and that the aggregate fire flow capacity be evaluated as per Technical Bulletin ISTB-2018-02.

7.5 Investigations of Additional Servicing Strategies (2031)

Two (2) additional servicing strategies were investigated under the 2031 development scenario. The first servicing alternative was evaluated to assess its effectiveness in improving the level of service in the BSUEA while the second scenario was investigated to assess the reduction in the level of service should the construction of one of the feedermains be delayed. These servicing strategies are as follows:

1) First, additional servicing strategy would consist of the construction of a dedicated 300 mm diameter feedermain to the BSUEA along Barnsdale Road. This feedermain would connect the Rideau Valley Drive 400 mm diameter feedermain to the proposed 200 mm diameter feedermain along Barnsdale Road (refer to Section 7.5.1). Given that a second feed to Manotick Village from the Riverside South Community is expected in the future, this servicing option could potentially provide an increase in the operating pressures; and
2) Second, additional servicing strategy would assess pressures under the 2031 development scenario without the 300 mm diameter feedermain along New Greenbank Road, which would be assumed to be delayed beyond 2031 (refer to Section 7.5.2).

7.5.1 Implementation of Barnsdale Road 300 mm diameter feedermain

This servicing alternative was developed and evaluated to determine whether an additional feedermain originating from Manotick Village could improve pressures in the BSUEA in an attempt to reduce and/or eliminate the area exhibiting sub-standard pressures during PKHR (refer to Figure 7-10 for area). This servicing alternative entails the construction of a 300 mm diameter feedermain connecting the local 200 mm diameter Barnsdale watermain to the existing 406 mm diameter feedermain along Rideau Valley Drive. This proposed 300 mm diameter feedermain would follow the Barnsdale Road ROW from existing Greenbank Road easterly to its connection with Rideau Valley Drive.

The performance of the proposed distribution system was evaluated under the 2031 development scenario under the: i) PKHR (minimum hour), and ii) PKHR (average) conditions. Simulation results under this servicing strategy have shown the following:

- Under the PKHR demand scenario, the minimum pressures during this 72-hour simulation (Figure 7-13) range between 32.8 psi (226 kPa) and 51.5 psi (355 kPa). Simulation results show a slight increase in the operating pressures of 0.6 psi (4 kPa) resulting from the construction of this new Barnsdale Road 300 mm diameter feedermain. In general, the same nodes as the main servicing scenario, located west of New Greenbank Road will still exhibit pressures below the minimum pressure criterion of 40 psi (276 kPa);

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\GIS\26610 C PeakHourMin_Manotick.mxd

Plot Date: May 3, 2018 8:46:44 AM

- Under the PKHR demand scenario, the average pressures during this 72-hour simulation (Figure 7-14) range between 37.0 psi (255 kPa) and 55.5 psi (383 kPa). Specifically, the same four (4) nodes that do not satisfy the minimum pressure constraint of 40 psi (276 kPa) under the main servicing scenario. These nodes are located in the southwest quadrant of the Kilbirnie Drive extension and New Greenbank Road intersection.

A further review of the above peak hour simulation results has revealed that the proposed Barnsdale Road 300 mm diameter feedermain would supply potable water easterly, from the BSUEA to Rideau Valley Drive. As a result, the supply to Manotick would benefit the most while the level of servicing of the BSUEA would virtually remain the same. Consequently, this servicing alternative was not further pursued.

7.5.2 Assessment of Level of Service without New Greenbank Road Feedermain

Simulation results under the 2031 development scenario have so far been completed assuming that the 400 mm diameter feedermain along New Greenbank Road would be in operation. Although funds appear to be available for this capital project, there is no certainty on timing. An alternate servicing alternative was, therefore, investigated assuming the New Greenbank Road 400 mm diameter feedermain would not be operational under the 2031 scenario.

The performance of the proposed distribution system was, therefore, evaluated under the 2031 development scenario for the: i) PKHR (minimum hour), and ii) PKHR (average) conditions. Simulation results under this servicing strategy have shown the following:

- Under the PKHR demand scenario, the minimum pressures during this 72-hour simulation Figure 7-15 range between 32.1 psi (221 kPa) and 50.7 psi (350 kPa). In general, all nodes west of and including New Greenbank Road will exhibit pressures below the minimum pressure criterion of 40 psi (276 kPa). Similarly, the western portion of the Mattamy Lands East will also exhibit pressures below the 40 psi (276 kPa) criterion;
- Under the PKHR demand scenario, the average pressures during this 72-hour simulation (Figure 7-16) range between 37.6 psi (259 kPa) and 56.1 psi (387 kPa). Specifically, there are four (4) nodes that do not satisfy the minimum pressure constraint of 40 psi (276 kPa). Similar to the 2031 scenario with New Greenbank Road, these nodes are located in the southwest quadrant of the Kilbirnie Drive extension and New Greenbank Road intersection.

- This servicing strategy (without Greenbank Road) was found, in general, to be capable of delivering fire flows in excess of 13,000 L/min (217 L/s) within the BSUEA during a maximum day demand as shown on Figure 7-17. The exception is two (2) nodes located within the Mattamy Lands East that do not meet the system level fire flow of 13,000 L/min (217 L/s); however, those nodes exceed the minimum cap of 10,000 L/min (167 L/s). Given that the nodes are located within the Mattamy Lands East, next to New Greenbank Road, and that fire flow at the boundary of the property exceed 21,900 L/min (365 L/s), it is recommended that hydrant spacing be carried out to locate proposed hydrants closest to existing Half Moon Bay rather than New Greenbank Road. This servicing approach would increase fire flow availability within the Mattamy Lands East. It is recommended that hydrant spacing be reviewed closely at detailed design to maximize fire flow availability and that the aggregate fire flow capacity be evaluated as per Technical Bulletin ISTB-2018-02. There is also an additional node along New Greenbank Road that does not meet either the cap fire flow or the system level fire flow. However, this node would not represent a hydrant as it is located on the opposite side of the arterial and would not be operational. As previously noted

7.6 Water Servicing Evaluation

Table 7-7: Water Servicing Evaluation

Issue	Aspect	Advantages
Geotechnical Issues and Construction Risks	Potential for poor soils/rock/elevated groundwater table, etc.	Standard watermain depth will be above water table
Infrastructure Requirements	Extent of works required	Works are contained to those within the BSUEA
Operational Impacts	Extent of maintenance intensive infrastructure	Standard watermain design
Property Acquisition / Land Use	Ease of property acquisition / compatibility with demonstration plan	Servicing is contained within proposed corridors and servicing parcels
System Reliability	Level of redundancy within system	Watermain trunk loop has two connection points
System Flexibility	Ability to adapt to changes in demonstration plan	Watermain can adapt to ROW corridor changes but connection points are set
Displacement of existing land uses	Effects in removal of existing communities	All work is within the BSUEA
Disruption to existing land uses	Extent of works affecting existing communities	All work is within the BSUEA
Consistency with City Infrastructure	Compatibility with City Design Guidelines and IMP	Adheres to local and provincial design guidelines
Impact on Significant Natural Features	Loss of natural areas due to servicing	Adheres to land use and demonstration plans
Impact on Aquatic Systems	Potential impact of water quality in receiving watercourses	No watercourse crossings
Impact on Surface Water and Groundwater	Minimization of works in waterbodies or in the groundwater table	No watercourse crossings
Effects on Urban Green Space, Open Space and Vegetation	Disruption or loss of green space or trees due to servicing	Follows land use and demonstration plans
Efficiency of Proposed Infrastructure	Use of existing or combined corridors	Extension of existing system with no upgrades required
Efficiency with Existing Infrastructure	Use of existing infrastructure or capacity	Extension of existing system with no upgrades required
Capital Costs	Initial Construction Cost	Standard watermain at standard depths

Issue	Aspect	Advantages
Operating Costs	Ongoing operation and maintenance requirements	No projected additional booster pump or reservoir infrastructure
Issue	**Aspects**	**Disadvantages**
Operational Impacts	Extent of maintenance intensive infrastructure	Standard watermain design however with mitigation measures for low pressure areas
Phasing and Scheduling	Integration with development phasing	Watermain looping may be required to achieve pressures regardless of phasing.

7.7 Water Summary and Recommendations

The proposed watermain servicing within the BSUEA lands is shown on Drawing MWM. A number of trunk watermain extensions are recommended as backbone to service the BSUEA lands. These watermains include:

- 400 mm diameter Greenbank Road Extension (from Existing at Knockaderry Crescent - Barnsdale Road);
- 300 mm diameter East-West Collector (Greenbank Road - Western limit of CDP);
- 300 mm diameter Kilbirnie Drive Extension (Alex Polowin Avenue - Park & Ride);
- 300 mm diameter Future Collector Road Extension (Northern Limit of Drummond - Kilbirnie Drive Extension);
- 300 mm diameter New Greenbank Road (Barnsdale Road - Northern limit of CDP); and,
- 300 mm diameter River Mist Road Extension (Northern CDP Limit - East-West Collector).

Water demands were spread over nine (9) nodes within the BSUEA. Demand allocation should be revisited at detailed design once all local watermains are added to the water model. At such time, it is recommended that all nodes include local water usage.

Watermain sizing has considered basic day demands as well as peak hourly demands, fire flow requirements and system redundancy. The proposed distribution system was evaluated against the requirements described in the Ottawa Design Guidelines for water distribution. The analysis confirmed that servicing of the BSUEA lands does not require any off-site watermains to support its development. However, mitigation measures are proposed (i.e., 25 mm diameter service lateral and oversized plumbing) for a residential area abutting the western perimeter of the Park and Ride facility. Although the minimum pressure constraint will not be achieved, the above recommended measures are appropriate to mitigate low pressures. Hence, it is recommended that this deviation to the Guidelines be accepted.

8.0 Impacts and Mitigation

The analysis and evaluation process completed and summarized in Sections 5.0 to 7.0 above has identified the preferred servicing strategy for the BSUEA as depicted on Drawings DSAN, MWM, KS1, KS2 and MSWMF. The evaluation process included assessment of indicators related to design, construction and operation, social, natural, and economic factors as summarized in Table 5-15, Table 6-5 and Table 7-7. The impacts of the preferred servicing strategy on the study area and the mitigation required are outlined in this section.

8.1 Design, Construction and Operation

8.1.1 Storm and Stormwater Management Servicing

The preferred storm servicing and stormwater management servicing strategy involves the use of an infiltration measure that will promote recharge of the overburden aquifer. The preferred infiltration method identified is the EES (refer to Section 5.5.1), relies on the exfiltration of minor system capture. By promoting infiltration of captured runoff via the EES and by achieving distribution infiltration of clean runoff (i.e., from local streets, relatively free of roadway salts), the following benefits will be achieved:

- Preservation of the pre-development infiltration regime (water budget) for each of the three (3) subwatersheds;
- Preservation of the baseflow characteristics;
- Mitigate adverse impacts on the esker;
- Reduce post-development peak flows, which in turn, will prevent increases in flood potential;
- Protect downstream water quality by infiltrating the first flush of the frequent storms;
- Remove the need for a water quality pond and associated safety concerns; and,
- Maintain quality of downstream aquatic resources by infiltrating the first flush.

The EES was implemented in 1993 in the former City of Etobicoke as part of a project retrofit. Although these systems require additional inspection, it has proven for the past 25 years of operation that the system is reliable and its maintenance very similar to a conventional system. Annual inspections part of or combined with a post-large storm event monitoring program, are required.

Due to the additional maintenance associated with an EES, there is a possibility that the BSUEA lands be serviced solely by a conventional storm sewer system, which will require end-of-pipe wet ponds. Should the conventional system and wet ponds be pursued, their operation and maintenance would be the same for similar systems within the City.

8.1.2 Sanitary Servicing

Sanitary servicing of the BSUEA lands has been described in greater detail in Section 6.0. The BSUEA will be serviced via extensions of the existing and/or planned wastewater collection system. Hence, there are no infrastructure needs to either increase downstream capacity or to implement pumping in order to achieve gravity connections. In terms of operation, the extension of the gravity systems within the BSUEA lands will require standard operation and maintenance for similar systems within the City.

8.1.3 Water Servicing

Water servicing of the BSUEA lands has been described in greater detail in Section 7.0. The BSUEA will be serviced via extensions of the existing and/or planned watermains. Hence, there are no infrastructure needs to either increase downstream capacity of delivery or to implement pumping to service high areas. In terms of operation, the extension of the water distribution system within the BSUEA lands will require standard operation and maintenance for similar systems within the City.

9.0 Class EA Project Listing

9.1 Environmental Assessment Projects

The infrastructure conceptually sized as part of this MSS process satisfies the requirements of Phases 1 and 2 of the Class EA process as outlined in Sections 1.3 and 2.0. The infrastructure projects, which will be required to be undertaken, are listed in this section of the report.

All the projects listed in this section will fall under the Environmental Assessment Act and will require an Environmental Compliance Approval (ECA) from the Ministry of the Environment and Climate Change (MOECC). Since the BSUEA CDP process follows the Class EA process, review agencies and the public will have an opportunity to review the documentation being prepared and appeal to the Ontario Municipal Board (OMB). The opportunity to appeal to the OMB will occur following the Notice of Completion, which will also include the conditions of planning approvals as well as the Class EA documents. This can be explained by the fact that both the development and review process is being integrated with the Planning Act and development application process.

Appeals to the OMB can be made to any of the OP and zoning by-law amendments or to the approval of subdivisions, as stipulated in the Planning Act. A Part II Order (PIIO) request may also be made to the MOECC or a delegate. However, when reviewing a PIIO request, the purpose and intent of the integration provisions – to co-ordinate the requirements of the Planning Act within the Class EA – will be considered. If any projects are appealed to the OMB, then the OMB will have to render a decision, allowing the project to proceed before the requirements of both the development approval process and the Class EA process are deemed to have been satisfied.

Once the notice period is complete (or a decision to proceed has been made as a result of an appeal), the Class EA documents and the preferred projects listed below will not be subject to any additional EA approval requirements with following submissions, unless there are major changes (Section 11.1). At this stage, the projects will be able to proceed to construction without any additional Class EA requirement.

9.1.1 Stormwater Management and Servicing Projects

The Schedule ‘B’ projects include:

- Trunk storm sewers along New Greenbank Road, from future Kilbirnie Road extension (MH172) to future East-West Collector (MH152);
- Trunk storm sewers along New Greenbank Road, from future East-West Collector (MH152) to Barnsdale Road (MH176);
- Trunk storm sewers along future East-West Collector, from western CDP limit (MH150) to Wet Pond 1;
- Trunk storm sewers along future ROWs and easements north of Barnsdale Road, from western CDP limit (MH120) to Wet Pond 2;
- Trunk storm sewers along future Street 1, from local road (MH114) to future East-West Collector (MH154);

- Water Quality Treatment Unit at Kilbirnie Drive west of Polowin Avenue (MH710);
- Wet Pond 1 abutting Greenbank Road and Knockaderry Crescent;
- Wet Pond 2 abutting Greenbank Road and Barnsdale Road;
- Spill-over dry pond 1 abutting Barnsdale Road;
- Spill-over dry pond 2 within the Mattamy Lands West near the future Dundonald Drive extension;
- Quantity Storage and water quality treatment for Brazeau lands;
- Quantity Storage and water quality treatment for Drummond lands; and,
- Pilot project that includes an Etobicoke Exfiltration System (EES) along a local road. The exact location and length of the system to be determined at first phase of Draft Plan of Subdivision.

In the event that the EES be accepted by the City, the above-noted projects should be replaced by the following:

- Trunk storm sewers along New Greenbank Road, from i) future Kilbirnie Road extension (MH172) to future East-West Collector (MH152),and ii) Barnsdale Road (MH177) to future East-West Collector (MHMH152);
- Trunk storm sewers along future East-West Collector, from western limit of CDP (MH150) to Dry Pond 2;
- Trunk storm sewers along future ROWs and easements north of Barnsdale Road, from western CDP limit (MH320) to Wet Pond 2;
- Trunk storm sewers along future Street 1, from local road (MH314) to future East-West Collector (MH154);
- Water Quality Treatment Unit at Kilbirnie Drive west of Polowin Avenue (MH710);
- Dry Pond 1 abutting Greenbank Road and Knockaderry Crescent;
- Dry Pond 2 abutting Greenbank Road and Barnsdale Road.
- HDS at MH158 and downstream of MH336;
- Spill-over dry pond 1 abutting Barnsdale Road; and
- Spill-over dry pond 2 within the Mattamy Lands West near the future Dundonald Drive extension;
- Quantity Storage and water quality treatment for Brazeau lands;
- Quantity Storage and water quality treatment for Drummond lands; and,
- Local roads to be serviced with an EES.

9.1.2 Wastewater Servicing Projects

The Schedule 'B' projects include:

- Trunk wastewater sewers along future East-West Collector, from the western limit of the CDP (MH550) to Greenbank Road (MH119);
- Trunk wastewater sewers along the eastern perimeter of the French Catholic Elementary School, from Barnsdale Road (MH536) to future East-West Collector (MH557);
- Trunk wastewater sewers along future Street 1, from MH 514 to future East-West Collector (MH554);

9.1.3 Water Distribution Projects

The Schedule 'B' projects include:

- 300 mm trunk watermains along future Kilbirnie Drive extension, from Alex Polowin Avenue to the western limit of the CDP trunk watermain from future Kilbirnie Drive extension through a local road to the Brazeau Pit;
- 300 mm trunk watermains along the future East-West Collector, from Greenbank Road to the western limit of the CDP;
- 300 mm trunk watermains along the New Greenbank Road, from the northern limit of the CDP to Barnsdale Road;
- 300 mm trunk watermains along the River Mist Road extension, from future East-West Collector to the northern limit of the CDP; and
- 400 mm trunk watermains along Greenbank Road, from Knockaderry Crescent to Barnsdale Road

9.2 Development Applications and Approvals

The development application that is to be made to the City will be reviewed in accordance with the policies outlined in Section 4 of the OP. The specific studies required under the development approval process are determined at the commencement of the process at a pre-application consultation meeting with City staff. Studies required may include geotechnical studies, community transportation and traffic studies, noise studies, servicing and stormwater management studies, and environmental impact studies. A number of the studies that are likely to be required have already been completed as part of the CDP and it is generally accepted that these can be used as part of the development approvals process for a five (5) year period following completion of the respective study.

A planning rationale outlining how the development meets the intent of the overarching plans for the area, including the OP, this BSUEA CDP and City design guidelines, is usually required.

9.3 External Agency Approvals

9.3.1 Ministry of the Environment and Climate Change

An ECA from the MOECC is required under the Ontario Water Resources Act for all sanitary sewers, storm drainage located along ROWs as well as for any SWMFs.

9.3.2 Ontario Drainage Act

Any modifications to the hydrological regime or alteration to the municipal drains within the Mud Creek and Rideau River subwatersheds will need to be documented in an Engineers Report by the Engineer of Record as per the Drainage Act (Section 78, Chapter D.17, R.S.O. 1990).

9.3.3 Rideau Valley Conservation Authority (RVCA)

The RVCA will review the development applications to ensure that it is consistent with the conservation, development and management of natural resources within the Rideau River watershed. In addition, they will ensure that property and people are protected from hazards such as flooding and erosion.

9.3.4 Ministry of Tourism, Culture and Sport (MTCS)

Application for Archaeological Clearance for Stage 1 Archaeological Assessment and Stage 2 must be made to the MTCS.

9.3.5 Ministry of Natural Resources and Forestry (MNRF)

Registration of a project and/or a permit is required with the MNRF where there may be disruption to a Species at Risk as part of the Ministry's Endangered Species Act (S.O. 200, c.6).

9.4 Development Charge Projects

Development Charges (DCs) are a one-time fee imposed by municipalities under the Development Charges Act. They are reviewed and set every five (5) years as part of a DCs by-law by the City. The charges are imposed on new residential and non-residential properties to cost share a portion of the growth-related capital infrastructure requirements. Once adopted by the City, this CDP can be used to include items in the development charge due to the increased need for services contained in the CDP. The following is a list of projects within the BSUEA that are eligible to be included in a development charges study:

- New Greenbank Road;
- Oversizing of sanitary sewers if larger than 375 mm and conveying flows in excess of 80 L/s;
- Oversizing of watermains if larger than 405 mm diameter; and,
- Land acquisition for Park and Ride.

10.0 Opinion of Probable Cost

10.1 Cost Comparison Between Conventional and EES Storm Sewer Systems

An Opinion of Probable Cost (OPC) for the Conventional and the EES storm sewer systems was completed to compare the cost between the two (2) systems. Only items which differed between the two (2) systems were included in the cost comparison provided in Appendix K. Storm sewers were, excluded from the OPC since sewer sizes are considered to be the same between the two systems.

The main difference between the two systems is the inclusion of the perforated pipe, clear stone and geotextile below local storm sewers in the EES, as shown on the cross sections on the Detail Drawing DT1. The exfiltration system requires deeper trenches which have also been accounted for in the cost comparison. In addition to the exfiltration system, the comparison also includes water quality controls including the water quality units in the case of the EES and the excavation for the permanent pool in the case of the conventional system.

As shown in the detailed cost comparison spreadsheet presented in Appendix K, it is anticipated that an EES for the BSUEA will have a construction OPC of approximately $3.45M over than a conventional storm sewer system (including a 40% contingency), which is equivalent to $293 per linear meter of road based on 11.8 km of road.

10.2 Cost Sharing of trunk storm sewers

It is anticipated that trunk storm sewers servicing New Greenbank Road and the Park & Ride will be eligible for cost sharing between Minto and the City. A theoretical cost sharing amount was estimated for both the conventional sewer system and the EES option based on the extent of trunk storm sewers that were oversized to accommodate runoff generated by the New Greenbank Road ROW and the Park & Ride.

10.2.1 Conventional Storm Sewer System

In terms of the conventional storm sewer system, the Park & Ride and the New Greenbank Road ROW are tributary to trunk storm sewers along Kilbirnie Drive, New Greenbank Road and the southern limit of the BSUEA/Barnsdale Road. If the Park & Ride and New Greenbank Road drainage areas (totalling approximately 6 ha) are excluded from the system, then storm sewers can be reduced in size, as indicated Table 10-1 below.

Table 10-1: Sewer Size Comparison with and without Park & Ride and New Greenbank

Street/Location	Upstream MH	Downstream MH	Pipe Size (mm) INCLUDING P&R and New Greenbank	Pipe Size (mm) EXCLUDING P&R and New Greenbank
Kilbirnie Drive	170	172	900	900
New Greenbank Road	172	174	1350	975
New Greenbank Road	174	176	1350	975

New Greenbank Road	176	179	1350	975
New Greenbank Road	179	178	1800	1500
Southern Limit of BSUEA	178	132	1950	1650
Southern Limit of BSUEA	132	134	1950	1800
Barnsdale Road	134	136	1950	1800
Barnsdale Road	136	137	1950	1800
Southern Limit of BSUEA	137	P2-In	1950	1800

An OPC was prepared for the aforementioned trunk sewers and is presented in Appendix K. The OPC estimates are based on both sewer and maintenance hole sizes for a storm sewer system with and without the Park & Ride and New Greenbank Road drainage areas. The OPC estimate for each option is presented in Table 10-2 below. Note that the estimated costs include a 40% contingency.

Table 10-2: Trunk Storm Sewer Estimated Cost Comparison

	Opinion of Probable Cost
Trunk Sewers/MHs INCLUDING P&R and New Greenbank	$3,240,000
Trunk Sewers/MHs EXCLUDING P&R and New Greenbank	$2,656,000
Difference (City Share)	$584,000

Based on the above OPC, the oversizing of the BSUEA sewers to accommodate runoff generated by the Park & Ride and New Greenbank Road will be approximately $584,000. Hence, the City's proportionate share of the BSUEA trunk storm sewer works, for the conventional system, is estimated to be $584,000.

10.2.2 Storm Sewers with EES

In the EES servicing option, the Park & Ride and the New Greenbank Road ROW are tributary to trunk storm sewers along Kilbirnie Drive, New Greenbank Road and the East-west Collector. If the Park & Ride and New Greenbank Road drainage areas (totalling approximately 6 ha) are excluded from the system, then storm sewers can be reduced in size, as indicated in Table 10-3 below.

Table 10-3: Sewer Size Comparison with and without Park and Ride and New Greenbank Road

Street/Location	Upstream MH	Downstream MH	Pipe Size (mm) INCLUDING P&R and New Greenbank	Pipe Size (mm) EXCLUDING P&R and New Greenbank
Kilbirnie Drive	170	172	900	900
New Greenbank Road	172	174	1350	975

New Greenbank Road	174	176	1350	975
New Greenbank Road	176	152	1350	975
New Greenbank Road	177	152	675	N/A[11]
East-west Collector	152	154	1500	1050
East-west Collector	154	156	1500	1050
East-west Collector	156	158	1500	1200
East-west Collector	158	P2-In	1500	1200

An OPC was prepared for the aforementioned trunk sewer systems and is presented in Appendix K. The OPC estimates are based on both sewer and maintenance hole sizes and were completed for a storm sewer system with and without the Park & Ride and New Greenbank Road drainage areas. The OPC for each scenario is presented in Table 10-4 below. Note that the estimated costs include a 40% contingency.

Table 10-4: Trunk Storm Sewer Estimated Cost Comparison

	Opinion of Probable Cost
Trunk Sewers/MHs INCLUDING P&R and New Greenbank	$2,178,000
Trunk Sewers/MHs EXCLUDING P&R and New Greenbank	$1,680,000
Difference (City Share)	$498,000

Based on the above OPC estimates, the oversizing of the BSUEA storm sewers to accommodate runoff generated by the Park & Ride and New Greenbank Road is $498,000. Hence, the City's proportionate share of the BSUEA trunk storm sewer works, for the EES servicing option, is estimated to be $498,000.

10.3 Development Charge Infrastructure Projects

Development charges are one-time fees levied by municipalities on new residential and non-residential properties to help pay for a portion of the growth-related capital infrastructure requirements. (City of Ottawa, 2017)

It is anticipated that some of the proposed trunk storm sewers in the BSUEA which are equal to or greater than 1800 mm in diameter may be eligible for Development Charge (DC) repayment, according to the current 2014 DC By-law. In terms of the Conventional storm sewer system option, this would apply to storm sewers on New Greenbank Road (245 m), the East-West Collector (215 m) and the southern limit of the BSUEA/Barnsdale Road (695 m). With regard to

[11] Sewer segment between MH 177 and 152 services solely the New Greenbank Road ROW, therefore, with this drainage area excluded, the sewer segment is not required.

the EES option, all of the proposed trunk storm sewers are less than 1800 mm in diameter and would, therefore, not qualify for DC recoveries.

The City of Ottawa 2014 Development Charges Study Report Update indicates that the benchmark for DC repayment for sanitary sewers is applicable to sewers equal to or greater than 450 mm in diameter with peak flows greater than 80 L/s. Although there are sanitary sewers that are 450 mm diameter and greater that are proposed to service the BSUEA, none of these sewers will convey peak flows greater than 80 L/s. On this basis, none of the proposed BSUEA sanitary sewers would qualify for DC recoveries.

DC repayment for watermains applies to watermains equal to or greater than 610 mm in diameter. DC repayment for watermains in the BSUEA would, therefore, not apply since the maximum watermain size proposed within the BSUEA is 406 mm in diameter.

The DC By-law also applies to ROWs which have a travelled roadway section that is wider than 11 m. Should Minto front-end the construction of the New Greenbank Road ROW then it is anticipated that the New Greenbank Road ROW would qualify for DC recoveries based on the EA ROW cross sections shown on Details Drawing DT1.

The eligibility for DC recovery of all proposed infrastructure servicing the BSUEA should be re-assessed upon passing of the updated DC By-law anticipated for 2019.

11.0 Implementation and Phasing

11.1 Adaptability of the MSS within the EA Amendment Process

As per section 9.1, once the Class EA has been approved, construction of services can proceed. However, it is acknowledged that there may be changes prior to the construction being completed. The development should proceed as per the Class EA or as consistent with the intent of the approved Class EA as possible. If circumstances arise that were not anticipated or could not be clearly foreseen, this may trigger changes to the MSS as approved. There are two (2) classes of changes that may occur: i) minor changes that do not have significant changes to the environmental impacts of the work and which remain as per the intent of the EA, and ii) major changes which substantially change the environmental impacts. Conversely, a major change would require an addendum to the MSS which would outline the implications for the change, and would have to be made available for public review.

The nature of major and minor changes is set out further below.

11.1.1 Minor Changes

These include changes that could be considered to be typical and arise frequently on projects as the project is refined through the detailed design and planning process. Changes in alignments or footprints could also be considered minor provided that they do not adversely impact other landowners. Minor changes are approved through the City's development review process.

11.1.2 Major Changes

Deviations from the CDP and MSS that would substantially alter the impact to the environment are deemed as major changes. Major changes can also occur when the environmental conditions for the project change, which will have a significant impact on the environment. Major changes could include the requirement for pump and/or booster stations or the discovery of Species at Risk.

Should a major change occur, then the EA's recommendations and conclusions would need to be updated. This process would have to be carried out through an amendment to the EA. The amendment would identify the associated impacts of the change and the proposed mitigation measures. Following review and input by the stakeholders and external agencies, a Notice of the Addendum would need to be posted and would be open to public review. It should be noted that only the parts of the EA where changes occurred would be subject to public review. All other parts could not be reviewed.

11.2 Detail Design

The objective of the MSS is to provide a high level servicing solution, which can demonstrate that development is feasible in accordance with municipal and provincial standards. Street-by-street detailed design would still be required; however, this process would occur at the Plan of Subdivision or Site Plan applications stage. Minor changes to the MSS design are expected to occur as further field information is processed and the design is further detailed, which could in turn impact grade raises and ROW grading

11.3 Infrastructure Phasing

It is intended that development generally proceeds from the eastern boundary of the CDP towards the west. In parallel, a portion of the study area located in the northwest corner adjacent to Half Moon Bay is also expected to proceed. The majority of the proposed services are intended to connect to existing services in the existing urban boundary on the western side of the CDP.

The intended phasing for the BSUEA is set out below and shown in Figure 11-1.

- Minto Lands
    - Phase 1: Minto Lands north of the East-West Collector and east of New Greenbank Road
    - Phase 2: Minto Lands south of the East-West Collector and east of New Greenbank Road
    - Phase 3: Minto Lands west of New Greenbank Road
- Mattamy Lands East
    - All one phase which could be constructed jointly with the Half Moon Bay South development.
- Mattamy Lands West
    - All one phase which could be constructed jointly with the Half Moon Bay West development.
- Brazeau and Drummond Aggregate Extraction Areas
    - Each Aggregate Extraction Area can proceed once filling up to the minimum rehabilitation elevation has been met although in terms of land use the restrictions around operating Aggregate Extraction Areas must continue to be adhered to until both areas stop operations.

The servicing needs for each of the three (3) services are set out below.

11.3.1 Storm Drainage and Servicing

11.3.1.1 Minto Lands under the conventional system

Phase 1 of the Minto Lands can proceed once Wet Pond 1 is in place and operational. The control orifice structure will need to be designed (size, location, etc.) and installed along the existing 1800 mm diameter storm sewer system of Quinn's Pointe, upstream of the Greenbank Road trunk sewer system. This proposed infrastructure will limit the pond's discharge.

11.3.1.2 Minto Lands under EES

Phase 1 of the Minto Lands can proceed once Dry Pond 1 is in place and operational. The control orifice structure will need to be designed (size, location, etc.) and installed along the existing 1800 mm diameter storm sewer system of Quinn's Pointe, upstream of the Greenbank Road trunk sewer system. This

DRAWING #:

FIGURE 11-1

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\GIS\26610 C PhasingPlan.mxd

Plot Date: April 30, 2018 3:29:47 PM

proposed infrastructure will limit the pond's discharge. To support the development of Phase 1, the hydro dynamic separator (HDS) located between both dry ponds will also need to be in place to provide quality control for the East-West Collector Road. In addition, a small cell of Dry Pond 2 will be required. Volume, shape and configuration of this cell to be determine at detailed design.

11.3.1.3 Mattamy Lands East

The Mattamy Lands East can be developed once the weir of the Todd Pond is increased from 30 m to 48 m in length as noted in the Todd Pond Model Keeper Analysis Re-Assessment of Existing System Capacity report (JFSA, 2015). The remainder of the servicing for the Half Moon Bay South Phase 4 subdivision must be in place and operational prior to the Mattamy Lands East servicing being operational.

11.3.1.4 Mattamy Lands West

The hydrological analyses completed have shown that a spill-over dry pond will be required prior to construction of the Mattamy Lands West unless sufficient street sag storage can be provided in the subdivision's grading.

11.3.2 Wastewater Servicing

The proposed BSUEA trunk sanitary sewers will discharge to existing/planned sanitary sewers at six (6) locations: The Future Collector Road, New Greenbank Road, Flameflower Street, Alex Polowin Avenue, Kilbirnie Drive, and Greenbank Road. Development will need to proceed from these points and extend westerly.

11.3.3 Water Supply Servicing

Water distribution systems are often vulnerable during the initial phases of development and as such the performance of Phase 1 was evaluated under peak hour and maximum day plus fire flow. Phase 1 would require the construction of part of the 400 mm and 300 mm diameter watermain extensions and local watermains.

The evaluation was carried out using the existing condition model (2016). Simulation results are as follows:

- Under PKHR condition, the minimum pressures during this 72-hour simulation (Figure 11-2) range between 42.8 psi (295 kPa) and 55.1 psi (380 kPa). Hence, all nodes within Phase 1 exceed the minimum pressure constraint of 40 psi (276 kPa); and
- Under a simultaneous maximum day and fire flow condition (Figure 11-3), fire flow availabilities, in general, exceed the minimum fire flow of 13,000 L/min or 217 L/s. However, there are two (2) nodes part of Phase 1 that will not meet the fire flow of 13,000 L/min. Both nodes are located within the Mattamy Lands East, and are the most western nodes next to New Greenbank Road. At those locations, fire flow availability of 187 L/s to 195 L/s was simulated.

Given that Peak Hour minimum pressures for Phase 1 are above 40 psi (276 kPa), fire flow availability exceeds the minimum fire flow cap of 10,000 L/min and that the minimum fire flow of 13,000 L/min (217 L/s) would be achieved met once the 300 mm diameter feedermain along New Greenbank Road is constructed, only local watermains need to be extended for Phase 1 to proceed. To increase fire flow availability in the Mattamy Lands East, it is recommended that hydrant spacing be carried out to locate proposed hydrants closest to existing Half Moon Bay rather than New Greenbank Road. By using this spacing approach, fire flow availability would be greater than what has been shown on (Figure 11-3).

12.0 Conclusions

This MSS has identified a recommended a high level servicing strategy for storm, wastewater and water servicing of the BSUEA CDP. The servicing strategy is a functional design which demonstrates the feasibility of servicing the proposed development. The design criteria utilized to develop the servicing strategy can be used to develop the detailed design. It is anticipated that the detailed design to be carried out in the Plan of Subdivision application phase, will be consistent with the MSS but will adapt for any alterations to the road and layout configurations. The MSS has been developed with this flexibility in the design.

Principal findings of the MSS are set out below:

Storm Drainage and Stormwater Management

- The design of the storm drainage system has been undertaken using the dual-drainage approach. The Master Servicing Study (MSS) sets out the design criteria for future draft plan and site plan applications for the BSUEA. The design criteria are consistent with current design standards.
- Two (2) separate storm servicing solutions were developed; one conventional servicing strategy and one that incorporates the Etobicoke Exfiltration System (EES), which was recommended. Should the performance of Phase 1's EES be inconclusive, then the feasibility of an infiltration gallery servicing the Phase 2 lands was reviewed. The high level assessment found that an infiltration gallery incorporated within the proposed spill-over dry pond next to Barnsdale Road could provide sufficient storage for part of Minto's Phase 2 lands.
- The downstream boundary conditions or flow criteria to achieve are developed in the MSS and were used in the design constraints.
- A preliminary grading plan was developed and used to depict drainage areas.
- The trunk sewer network was designed based on the preferred demonstration plan and modelled to ensure that the hydraulic grade line (HGL) elevations along the system maintained a 300 mm freeboard, which corresponds to 2 metres below proposed centreline elevations.
- Allowable minor system release rates were set at the required storm event and future design should maintain the same release rate criteria.
- The stormwater management solution incorporates two (2) stormwater management ponds adjacent to Greenbank Road, one spill-over dry pond west of the CDP boundary and a potential spill-over dry pond within the Mattamy West Lands.
- An additional two (2) potential stormwater management facilities have been identified in the stormwater management solution for the aggregate extraction areas.

Wastewater Servicing

- The residual capacities in the surrounding wastewater services were assessed to determine viable servicing outlets for the BSUEA wastewater.

- Six (6) outlet connection points have been identified for the BSUEA with sufficient residual capacity to provide wastewater servicing.
- The existing constructed and planned wastewater system network is capable to accommodate servicing for the BSUEA.
- Upsizing of some planned currently unconstructed wastewater infrastructure is recommended.
- The MSS contains design criteria which are to be used for the BSUEA in future draft plan and site plan applications. The design criteria are consistent with current design standards.
- The trunk wastewater system layout is designed based on the preferred demonstration plan and associated land use densities.
- The MSS servicing evaluation has identified that wastewater servicing of the BSUEA is feasible based on the downstream residual capacities and the proposed trunk sanitary sewer network.

Water Distribution

- The BSUEA can be serviced from the BARR pressure zone with watermain extensions from the surrounding existing watermains.
- The analysis confirmed that there are no upgrades to the planned distribution network identified in the 2013 Infrastructure Master Plan.
- Demand allocation for water supply servicing has been set at a high level based on the preferred demonstration plan and associated densities.
- Trunk watermain sizing has been carried out based on the demonstration plan and existing watermains at the boundary of the BSUEA lands.
- The BSUEA has set design criteria which is to be used for the BSUEA in future draft plan and site plan applications. The design criteria are consistent with current design standards.
- Mitigation measures are proposed for residential development with centreline elevations above 108 m to minimize the inconvenience of low minimum pressures in the distribution system above this elevation.

The MSS component of the BSUEA CDP satisfies the requirements of Phases 1 and 2 of the Municipal Class EA process. Infrastructure projects that will be undertaken as a result of development of the BSUEA, along with their phasing and schedule classification, are contained within the report.

The MSS demonstrates that the proposed CDP land use can be serviced by extending existing municipal water and wastewater infrastructure; upsizing planned future wastewater infrastructure, and constructing stormwater management facilities.

This report has been prepared for the exclusive use of Minto Communities Inc. and Mattamy Homes Ltd, for the stated purpose, for the Barrhaven South Urban Expansion Area. Its discussions and conclusions are summary in nature and cannot be properly used, interpreted or extended to other purposes without a detailed understanding and discussions with the client as to its mandated purpose, scope and limitations. This report was prepared for the sole benefit and use of Minto Communities Inc. and Mattamy Homes Ltd and may not be used or relied on by any other party without the express written consent of J.L. Richards & Associates Limited.

Barrhaven South Urban Expansion Area (BSUEA)
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

INTRODUCTION

Minto Communities (Minto) along with Mattamy Homes (Mattamy), herein referred to as the Owner, have retained a Consultant Team to undertake a series of deliverables in support of the Barrhaven South Urban Expansion Area Community Design Plan (CDP) process, which will be implemented as an Amendment to the City of Ottawa Official Plan (OP). The study process will include the Minto and Mattamy lands as well as the Brazeau and Drummond lands all within the limits of the Barrhaven South Urban Expansion Area (BSUEA). A number of deliverables will be prepared in support of the CDP, including an Existing Conditions Report (ECR), an Environmental Management Plan (EMP), a Community Transportation Study (CTS) and a Master Servicing Study (MSS) for water, wastewater, storm and stormwater management as well as site grading. The following Terms of Reference (TOR) have been revised to incorporate comments issued by the City on February 12, 2016. Task 1 described below relates to finalization of the TOR while Task 3 with the completion of the ECR and those associated with the preparation of the MSS in Tasks 3 to 5.

J.L. Richards & Associates Limited (JLR) was retained by Minto and Mattamy to complete part of the ECR that relates to water resources as well as the preparation of the MSS that will act as a supporting document to the Official Plan Amendment (OPA) and the CDP. The latter document will be completed to fulfill Phases 1 and 2 of the Municipal Class Environmental Assessment (MCEA) Process.

STUDY OBJECTIVES

The main objective of the JLR portion of this study is to develop a Master Servicing Study for the BSUEA that will fulfill the requirements of both municipal and provincial standards. Prior to preparing this Master Servicing Study, the first step of this study will be to review, evaluate and assess water resources in the area as well as the identification and evaluation of stream crossings and storm infrastructure. These tasks will be carried out at the onset of the study where findings will be consolidated and synthesized in the ECR. This document will also be supplemented by a series of biological findings, by Dillon, as well as a water budget analysis that will be completed by JLR in consultation with the hydrogeotechnical engineer. Once the ECR has been completed, the impact of the Barrhaven South Urban Expansion Area (BSUEA) on the existing services will be assessed and mitigation strategies considered, as part of the subsequent tasks and a preferred internal servicing plan will be identified from a series of alternatives.

The development of alternatives and selection of the preferred servicing alternative will follow the master planning process, where Phase 1 and 2 of the Municipal Class Environmental Assessment (MCEA) Process will be fulfilled. The preferred internal servicing plan will be developed to meet regulatory requirements and will be free of conflicts between the various

CANADA'S BEST MANAGED COMPANIES

infrastructure components (water, wastewater, storm and stormwater infrastructure). The following sections present the anticipated scope of work for JLR to complete the work noted herein for the following:

- Task 1 (Finalization of TOR),
- Task 2 (Existing Conditions Report),
- Task 3 (Vision, Objectives & Targets),
- Task 4 (Preliminary Concept Plans),
- Task 5 (Preferred Concept Plan, Demonstration Plan & Design guidelines,
- Task 6 (Barrhaven South Expansion Area Community Design Plan), and
- Task 7 (Implementation).

It should be noted that these TOR were prepared to satisfy Task 1 of the CDP process.

Barrhaven South Urban Expansion Area
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

TASK 1: FINALIZATION OF THE TERMS OF REFERENCE

The latest TOR (issued on December 3, 2015) was revised to integrate comments from the City and the RVCA issued on February 12, 2016. The following TOR document will form the basis of subsequent analyses to support the CDP.

TASK 2: EXISTING CONDITIONS REPORT

The scope of work to complete the Existing Conditions Report will include the following undertakings:

2.1 Review and Consolidate

To complete the ECR, the review of background reports that impact the Study Area will be completed. We anticipate that this review will include the following reports, which has been assumed that the documents would be provided in a digital format:

- Lower Rideau River Subwatershed Strategy (RVCA, 2005)
- Jock River Reach 1 and Jock River Reach 2 Subwatershed Plans (RVCA, 2007)
- Jock River Subwatershed Report (RVCA, 2010)
- Corrigan Storm Water Management Facility (CP), by IBI Group, dated July 2010
- Jock River – Barrhaven Catchment Data Sheet (RVCA, 2010)
- Mud Creek Subwatershed Study Existing Conditions Report, Phase 1 subwatershed (RVCA, 2011)
- Infrastructure Master Plan (City, 2013)
- Mud Creek Subwatershed Study, City of Ottawa (October 2015), approved by council in January 2016.
- Barrhaven South Master Servicing Study (Stantec, 2007)
- Barrhaven South Master Servicing Study Addendum Draft Report (Stantec, November 2014); document to be finalized in 2016
- Site Servicing Report, Quinn's Pointe, (J.L. Richards & Associates limited, July 29, 2015)
- Model Keeper Analysis for Todd Pond, (J.F. Sabourin and Associates Inc., updated 2015)
- Thomas Baxter Municipal Drain Engineer's Report
- Geotechnical Reports

Included in this task is the review of other information provided by the City and the RVCA. This would include, but not be limited to, mapping of surficial geology, hydrography, topography, LIDAR information, existing and upcoming topographical surveys (obtained on behalf of the Owner), floodplain mapping for the Jock River and Mud Creek, land use, vegetation, etc., as well as other data compiled by the Consultant Team's geotechnical engineer and biologist. Should information gaps be noted during

the completion of this task, JLR will inform the Owner.

2.2 Prepare Inventory of Water Crossings

Based on topographical survey completed by Stantec, JLR will compile and consolidate the data, in a standard report form, for the following water crossings along:

i) Barnsdale Road,
ii) Greenbank Road, and
iii) Cedarview Road.

2.3 Identify and Assess Capacity of Existing Conveyance Systems

Based on topographical maps/surveys and servicing reports of existing developments adjacent to limits of the CDP, free flowing capacity of watercourses (if any), roadside ditches and water crossings will be carried out.

2.4 Water Budget

In consultation with the hydrogeological engineer, JLR will carry out a Water Budget Analysis that will assess the balance between infiltration, runoff, and evapotranspiration under existing conditions. This analysis will be completed in accordance with the methodology described in Section 3.2 of the MOE publication entitled “Stormwater Management Planning & Design Manual, March 2003” using Environment Canada’s Thornthwaite Climatic Water Balance information derived from 30 years of monthly data. The existing conditions Water Budget Analysis will then be used as baseline condition as part of the MSS to predict/evaluate the potential changes to the hydrologic cycle resulting from urbanization.

2.5 Watershed Delineation

Upon the review of the background reports, the topographical maps/surveys and LIDAR compiled for the City, watersheds and sub-watersheds delineation will be carried out. If applicable, attention will be given to sub-watersheds that are found to be tributary to the Jock River versus those tributary to the Thomas Baxter Municipal Drain, one of Mud’s Creek tributaries.

2.6 Hydrological Modelling

Once the watershed limits have been further refined, a hydrologic model will be

developed to estimate peak flows and hydrographs under various recurrences for each sub-watershed and outlet. This analysis will be conducted with SWMHYMO under the design storm types and recurrences (1:2 year to 1:100 year) and hydrological parameters described in the Ottawa Sewer Design Guidelines. The analysis will consider the drainage features inventoried as part of the topographical survey (open ditch, culverts, etc.) as well as drainage divides between watersheds. Surface flows will be calculated based on the existing flow patterns for the various outlets; drainage ditches, culverts, and storm sewers, if applicable. Drainage Plans will be prepared depicting the various drainage features and sub-watershed limits as well as flow patterns and drainage patterns.

2.7 Floodplain Mapping

It is standard practice to hydraulically evaluate conveyance capabilities of watercourses as part of an ECR using models such as HECRAS, or HEC2. Results of this analysis include the calculation of water levels, which is in turn is used to delineate the 1:100 year floodplain limit.

Based on preliminary findings from the Consultant Team's biologist, there were no watercourses inventoried when the assessment for the "Headwater Drainage Features Guidelines" was completed as the various hydrography systems shown in the City's mapping within the BSUEA limit was non-existent. Hence, there is neither floodplain mapping nor water level calculations anticipated at this time. Should the final findings from the biologist show defined watercourses within the BSUEA, and then the 1:100 year floodplain would be generated based on the hydrological findings of Task 3.6 with the HEC-RAS software platform. Additional survey would then be required to gather geodetic data of the active channel and floodplain as well as at various water crossings. In this event, the floodplain (1:100 year) would be delineated on topographical maps.

2.8 Identification of Direct Watercourse Receivers and Geomorphological Assessment

As previously noted, there was no watercourse inventoried by the biologist within the limits of the BSUEA. The data collected to date show that a significant portion of the surface flows are either trapped/infiltrated on-site or sheet flows to a series of open ditches/culverts; some of which appear to convey flows westerly along Barnsdale towards Highway 416 and others easterly towards Greenbank Road, where the open ditch system flowing north is intercepted by the Greenbank Road trunk storm sewer system near Kilbirnie Drive. The existing condition drainage patterns will be confirmed when mapping and topographical surveys are reviewed. At this time, it appears that there will not be any need to carry out a geomorphological assessment of the receiving stream nor to investigate potential thermal impacts. Should there be a need identified during the course of the preparation of the ECR or MSS, the Owner will retain the services of a geomorphologist to carry out a geomorphological assessment and thermal

impacts would further be investigated with the assistance of the biologist.

2.9 Coordination and Liaise with Other Disciplines

The EMP and ECR will consolidate findings from all disciplines including, surficial geology, hydrogeology, water budget, hydrology, ecology (aquatic resources and natural areas), etc., which will establish the existing environmental conditions. Since the existing conditions hydrological regime is often influenced by natural environmental features, there will be efforts dedicated to coordinate and liaise with the other disciplines. The coordination will ensure that the hydrologic analysis considers natural environmental inventories and constraints.

2.10 Identify Constraints/Opportunities and Recharge/Discharge Areas

Based on the findings from the various disciplines, drawings will be prepared by each discipline to identify natural resources, existing conditions constraints and potential opportunities, which may impact storm and stormwater servicing or other municipal infrastructure. Similarly, recharge and discharge areas will be identified and depicted by others based on the hydrogeologist's findings.

2.11 Evaluation and Assessment of Storm Design Criteria and Objectives

Based on the findings of the natural resource inventories, storm criterion for both water quality and quantity will be established from a consensus with other disciplines. Once adopted by the Consultant Team, the storm criteria will be presented and confirmed by regulatory agencies during one of the scheduled meetings. The design criteria will be established to protect/enhance the environmental resources.

2.12 Assist Drainage Engineer with Hydrological Calculations for the Thomas Baxter Municipal Drain

Should the refinement of the watershed limits show that surface flows from part of the BSUEA is currently tributary to the Thomas Baxter Municipal Drain and that the divide is found to differ from the Drainage Report on record (January 1967), then there might be a need for the Owner to retain the services of a Drainage Engineer licensed under the Ontario Drainage Act to update the above Drainage Report. If this requirement is confirmed, JLR acting as the hydrological engineer will coordinate and prepare information requested by the Drainage Engineer to serve as background to an amendment to the Drainage Report.

2.13 Attend Core Project Team (CPT) and Technical Advisory Committee (TAC) Meetings

To facilitate coordination between all disciplines, project meetings will be scheduled with other disciplines. JLR intends to meet and liaise with the geotechnical and hydrogeological engineer as well as the biologist. To supplement the above, there will be one CPT meeting and one TAC meeting that will be held to obtain feedback from other disciplines and to identify any gaps in the records. It is also anticipated that pre-consult meeting(s) will be held with both MOECC and RVCA to identify whether supplemental inventories are required. These meetings will be held during the course of this task and prior to the preparation of a Draft Existing Conditions Report.

2.14 Prepare Sections for the Draft Existing Conditions Report

Based on the Table of Contents developed by Fotenn/Parsons, JLR will prepare sections of the Existing Conditions Report, including figures/drawings, data collected for the water crossings, modelling input and output files, appendices, etc. The Report will also reflect the discussions held as part of the CPT and TAC meetings and the input received from the regulatory agencies.

2.15 Review Comments and Finalize the Existing Conditions Report

Upon the review of the comments issued from the TAC members and during the CPT, the Draft Existing Conditions Report will be revised to address comments made by the TAC and/or regulatory agencies such as RVCA and the MOECC on JLR's sections of the ECR.

Barrhaven South Urban Expansion Area
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

TASK 3: VISION, OBJECTIVES & TARGETS

This task will establish the Vision, Objectives and Targets for the upcoming CDP. From a Master Infrastructure Servicing perspective, this task will include a thorough consolidation of the documents listed in Section 3.1, investigate and quantify residual capacities and servicing constraints while keeping in mind the environmental constraints identified as part of the ECR. More specifically, it is envisioned that the following tasks be completed:

3.1 Coordinate and Liaise with Geotechnical Engineer

In consultation with the geotechnical engineer, JLR will:

- Review specific grade raise restrictions on a zone by zone basis to better understand the potential grading constraints versus potential land use;
- Review the soil's characteristics to better understand whether they are conducive to infiltration measures;
- Review the soil's structural capabilities from a support/strength perspective;
- Review the areas of either recharge or discharge potential; and
- Review of future potential pit rehabilitation along with its impact on both municipal infrastructure and water budget.

3.2 Coordinate and Liaise with the Hydrogeologist

In consultation with the hydrogeologist, the existing conditions water budget analysis will be reviewed in greater details to identify the zones conducive to infiltration measures. These measures could potentially be used to mitigate impacts on the hydrological regime. As part of this task, low impact development (LID) strategies will be reviewed, at a conceptual level, to determine their viability and effectiveness in maintaining the existing conditions water budget.

3.3 Coordinate and Liaise with Biologist

In consultation with the biologist, the environmental constraints described in Task 3.10 will be further reviewed to better understand their sensitivity and tolerances to various land uses and their proximity. Given that there were no watercourses inventoried within the limits of the BSUEA, the objectives and targets from a storm discharge perspective will be based on the on-site environmental constraints as well as the limitations of the downstream watercourses.

3.4 Review Topographical Maps and Survey and Complete Inventory of Existing Infrastructure

Once all constraints have been compiled as part of Tasks 3.1 to 3.3, a further review of topographical maps and surveys will be completed as well as the drainage patterns identified under existing conditions. As part of this task, existing services and outlets will be inventoried for wastewater, water and storm. The assessment of residual capacities for existing services is proposed to be conducted as part of Task 5. If required, additional survey data may be required to supplement as-built information.

3.5 Attend CPT No. 2 and TAC No. 2

Under this task, a Draft Vision, Objectives and Targets will be adopted based on the discussion that will be held as part of the CPT No. 2. Once adopted, it will be further reviewed and examined as part of TAC No. 2. It is also expected that the proposed storm discharge criteria (quantity and quality) will be confirmed by regulatory agencies as a part of the acceptance of the ECR.

3.6 Prepare and Attend POH No. 1

Once CPT No. 2 and TAC No. 2 are completed, the Consultant Team will prepare background material that will be made available for the first public consultation (POH No. 1). During this meeting, findings of the Existing Conditions Report will be presented. The second part of the meeting will be held as a workshop, which will facilitate an exchange between the TAC members and the community; the project will be introduced, and the community will be engaged in defining a Draft Vision, Objectives and Targets for the BSUEA lands. It should be noted that POH No. 1 will be a voluntary public consultation part of Phase 1 of the MCEA process.

Barrhaven South Urban Expansion Area
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

TASK 4: PRELIMINARY CONCEPT PLANS

After the completion of Tasks 3 and 4, the Consulting Team will develop preliminary CDP Concept Plans based on the findings of the ECR, comments compiled to date from the TAC members and the input received from the public during POH No. 1. At this stage of the project, conceptual servicing will be investigated for the preparation of the preliminary CDP Concept Plans. However, in regard to the pit areas, a more in-depth review of the ECR findings and the servicing requirements will be carried out in advance of developing the preliminary CDP Concept Plans. The evaluation will measure the extent of the rehabilitation works required to service the pit areas, which in turn will assist in proposing workable land use for this area. Consequently, the extent of the rehabilitation works required to service the pit areas and proposed land use will determine the level of effort required in evaluating the municipal servicing requirements described below in Section 4.2.

4.1 Attend CPT No. 3 and TAC No. 3

The preliminary CDP Concept Plans will be further reviewed by the Consultant Team as part of CPT No. 3. During this meeting, it is envisioned that the preliminary CDP Concept Plans will be refined based on the interaction between the disciplines. Once the meeting completed, the refined CDP Concept Plans will be adopted for presentation to the TAC.

The evaluation findings for the proposed CDP Concept Plans will be shared with other TAC members as part of the TAC No. 3 meeting. Once comments and feedback have been received and addressed, final CDP Concept Plans will be adopted and municipal servicing will be evaluated.

4.2 Evaluation of Municipal Servicing Requirements for the Selected Concept Plans

JLR will evaluate infrastructure servicing requirements in support of the selected CDP Concept Plans. The tasks envisioned include the following:

4.2.1 Grading

1. Develop a macro level Grading Plan for the Concept Plans based on the constraints identified by the geotechnical engineer.
2. Grading to be developed in accordance with the criteria described in the Design Guidelines.
3. Generate cut/fill volumes, on a macro level, for the Concept Plans.

4.2.2 Water Infrastructure

1. Confirm pressure objectives with the City along feedermains (300 mm diameter or larger) under both domestic and fire flow conditions.
2. Calculate domestic demands (average, maximum day and peak hour) based on "system level parameters" under the build-out condition of the proposed land use for the selected Concept Plans. The said parameters will be provided by the City.
3. Calculate theoretical domestic demands for a maximum of three (3) phases of development based on a comprehensive phasing strategy.
4. Acquire hydraulic boundary conditions at each of the connection points of the existing water distribution system. It is envisioned that three (3) sets of boundary conditions will be provided; one reflecting today's operating characteristics of the pressure zone (BAR pressure zone), one that reflects the future reconfigured pressure zone (3C pressure zone) as well as the projected 2031 operating condition.
5. Develop and populate a base water model (H2OMAP software platform) for the selected Concept Plans. The H2OMAP model will be set based on 3 phases of development assuming the extension of existing trunk feedermains.
6. Evaluate the performance of the distribution system against municipal requirements under domestic demand conditions for the Concept Plans and three development phases for both current and future supply characteristics of the pressure zone.
7. Evaluate the performance of the proposed distribution system under a maximum day plus fire flow conditions for the Concept Plans and three development phases for both current and future supply characteristics of the pressure zone in accordance with Technical Bulletin ISDTB-2014-02.
8. Review Stantec's findings of their high level water servicing analysis when incorporating water demands from the BSUEA. These findings are proposed to be presented in the Barrhaven South Master Servicing Study Addendum that will be finalized in 2016.
9. Assess and identify deficiencies and develop system upgrades, if required, to meet municipal requirements from both pressure and demand criteria. This will include the review of system upgrades and larger feedermains, at-ground tanks, new pressure zone, etc.
10. Identify whether there will be concerns with water quality under the three phases of development or at build-out of the BSUEA lands. If required, assess using H2OMAP's water age analysis.
11. Prepare a Water Servicing Plan for the CDP Concept Plans. This Servicing Plan will show watermains with nominal diameters of 300 mm and greater.
12. Identify any expected servicing block, easement, or property requirements for the City.
13. Conduct reliability analysis of the proposed system by evaluating the impact of feedermain breaks. Assess whether basic day flow plus fire flow can be fulfilled in the BSUEA.

14. Assess residual capacities, if any, for the 2031 planning horizon.
15. Summarize findings for the Water Component for presentation at workshop (Charrette meeting).

4.2.3 Wastewater Infrastructure

1. Based on the sanitary sewer outlets inventoried as part of Task 3, assess residual capacities.
2. Develop sewershed boundaries based on existing sanitary sewer outlets and topography.
3. Develop peak wastewater flows based on the land use and density using the Harmon equation and population projections for the different land uses associated with the Concept Plans (Fotenn).
4. Prepare a Sanitary Drainage Area Plan and Sanitary Design Sheets for each Concept Plan.
5. Review trunk sanitary sewer routes, establish preliminary invert elevations based on topography and existing outlets.
6. Prepare Sanitary Servicing Plan and assess impact of phasing on infrastructure.
7. Identify servicing constraints, potential crossing conflicts and adjust, as required once the Storm Servicing Plan has been completed.
8. Assess residual capacities, beyond the BSUEA population, under existing and the 2031 planning horizon based on those reported in Stantec's Draft Barrhaven South Master Servicing Study (2014).
9. Review Stantec's findings of their high level wastewater servicing analysis when incorporating the BSUEA. These findings are proposed to be presented in Barrhaven South Master Servicing Study Addendum that will be finalized in 2016.
10. Identify potential system upgrades.
11. Summarize findings for Wastewater Component for presentation at workshop (Charrette meeting).

4.2.4 Storm Servicing and Stormwater Management

1. Based on the ECR's findings, confirm storm design criteria (quantity and quality) with the RVCA, MOECC and the City and discuss potential impacts.
2. Review topographic survey and maps.
3. Based on the storm sewer outlets inventoried as part of Task 4, confirm outlet locations and inverts, and assess residual capacities and drainage patterns, etc.
4. Review existing conditions hydrological analysis to establish the baseline condition.
5. Finalize capacity assessment of existing surface outlets using desktop calculations.
6. In consultation with the model keepers (JFSA and IBI) or Stantec, assess residual capacities in existing systems using either XPSWMM or PCSWMM.

7. Determine minor and major system drainage boundaries for the Concept Plans based on residual capacities of the existing.
8. Carry out post-development Water Budget based on the Concept Plans.
9. Identify and assess water budget deficits for each Concept Plan.
10. In consultation with the hydrogeologist:
    - Investigate, at the conceptual level, the integration of low impact development (LID) strategies within the BSUEA based on zones identified by the hydrogeologist, in particular with the Kars esker,
    - evaluate potential infiltration measures, and
    - assess conceptually the performance of the LID strategies and infiltration measures with respect to the potential water budget deficits.
11. Based on the minor and major system boundaries, prepare post-development Storm Drainage Area Plan and Servicing Layout for each Concept Plan.
12. Rehabilitation and servicing of the aggregate pits will be reviewed and developed in consultation with the geotechnical consultant.
13. If proposed servicing impacts the Thomas-Baxter Municipal Drain (Spence Branch), JLR will liaise with; i) the team's biologist to assess the impacts under low flow conditions, and ii) the City's municipal engineer to discuss potential requirements under the Ontario Drainage Act.
14. Pending the impacts on the Thomas-Baxter Municipal Drain, there might be a need for the Owner to retain the services of a Drainage Engineer and to conduct a low flow analysis using a continuous hydrological model.
15. Calculate theoretical runoff coefficients & imperviousness based on proposed land uses.
16. Prepare Storm Sewer Design Sheets using the Rational Method to establish 1:5 and 1:10 year peak flows (arterials) for each Concept Plan.
17. Calculate the 1:5 year and 1:10 year inlet capture for the various types of land use and arterials.
18. Develop trunk storm sewer routes and assess trunk sewer sizes for the Concept Plans based on the Rational Method.
19. Based on the outlet sewers and topography, establish trunk storm sewer obverts and inverts for each Concept Plan.
20. Review and assess potential end-of-pipe solutions that would satisfy the storm criteria (water quality and quantity).
21. Review potential dry pond location(s) west of the future Greenbank Road to prevent major overland flow cascading onto the arterial.
22. Investigate and identify end-of-pipe locations for each Concept Plan.
23. Assess water quality storage requirements based on total imperviousness for the Concept Plans. Calculations to be carried out in accordance with protection level and SWMP type as defined in Section 3.3.3 of the MOE SWMPDM.
24. Assess on-site storage volume requirements based on topography, land use, and ROW widths. This assessment will dictate a design criterion for on-site storage.
25. Develop stage-storage-outflow relationship for each end-of-pipe solution to satisfy the water quantity criterion.
26. Based on the existing conditions peak flow analysis, evaluate storage volume

requirements to meet the storm discharge criterion for quantity control.

27. Based on the storage volume target obtained from the peak flow analysis, establish the facilities siting for the Concept Plans. Siting to be based on topography, soil type, groundwater conditions, etc. In addition, siting of facilities to consider sub-watershed boundaries and capacity constraints of the Drain and/or watercourse.
28. Based on the siting of the facilities, establish footprint of the end-of-pipe facilities in accordance with the guidance described in Section 4 of the MOE SWMPDM.
29. Design elements of the end-of-pipe facilities to be reviewed conceptually based on Section 4 of the MOE SWMPDM.
30. Prepare post-development hydrological model that incorporates on-site storage volumes, dry ponds along with the end-of-pipe controls.
31. Evaluate the effectiveness of proposed measures for the Concept Plans.
32. Conduct a post- versus pre-development peak flow analysis (1:2 year to 1:100 year, per OSDG) to demonstrate compliance with the storm discharge criterion adopted for the project. Adjust the control measures accordingly until the storm discharge criterion is achieved.
33. Provide a Drawing to Fotenn that identifies blocks dedicated for SWM for the Concept Plans.
34. Identify servicing constraints, potential crossing conflicts and adjust, as required.
35. Establish typical roadway sag configuration and conduct a major overland flow analysis to assess total depth of flow. The analysis will generate the 1:100 year dynamic flow depth to be combined with typical static storage as well as the climate change event (as defined in the Ottawa Sewer Design Guidelines).
36. Calculate potential underside of footings elevations along the roadways based on land use.
37. Export the computed hydrographs generated by SWMHYMO to XPSWMM (or PCSWMM).
38. Carry out a hydraulic grade line (HGL) analysis of the proposed storm sewer system to evaluate the freeboard between the potential underside of footings and the 1:100 year storm. The analysis is to include the evaluation under the climate change event in accordance with the OSDG.
39. Assess impact of phasing on proposed storm infrastructure.
40. Export XPSWMM's (or PCSWMM) outflow hydrographs at each outlet; data to be provided to the model keeper of the Corrigan SWMF and Todd Pond.
41. Summarize findings for Stormwater Management Component for presentation at workshop (Charette meeting).

4.2.5 Opinion of Probable Cost (OPC) and Phasing

1. Coordination with other disciplines to finalize phasing for the Concept Plans in regard to servicing constraints.
2. Prepare an opinion of probable cost for municipal servicing for the Concept Plans.

4.3 Workshops (Design Charette)

It is anticipated that an open-discussion workshop meeting (Design Charette) will be conducted during Task 5. Topics discussed will include proposed infrastructure routes, location and type of end-of-pipe facility(ies), servicing alternatives and infrastructure requirements as well as comments and feedback received during the first meeting. Once comments and feedback have been received during both meetings, the municipal infrastructure servicing will be finalized for the Concept Plans.

4.4 TAC No. 3

The evaluation of servicing alternatives for the final Concept Plans will be shared with other members from the TAC as part of TAC No. 3 meeting. During this meeting, servicing alternatives and requirements will be discussed and comments will be sought. Once reviewed and revisions made, the servicing alternatives and requirements will be adjusted and finalized.

4.5 Prepare and Attend POH No. 2

Once the servicing alternatives for the CDP Concept Plans have been finalized based on the comments received at TAC No. 3, the information will then be presented to the public as part of POH No. 2, which will be advertised as the mandatory Public Open House under Phase 2 of the Class EA. At that meeting, the findings of the Final Existing Conditions Report will be provided to the community and their comments will be sought with respect to the CDP Concept Plans and their associated servicing evaluation.

4.6 Selection of Preferred Concept Plan

Once comments from POH No. 2 have been received, consolidated and integrated, a preferred Concept Plan will be recommended and presented to the CPT by the Consultant Team.

TASK 5: PREFERRED CONCEPT PLAN, DEMONSTRATION PLAN & DESIGN GUIDELINES

As part of this task, the preferred Concept Plan selected as part of Task 5 will be further refined and the Consultant Team will develop a Demonstration Plan and associated Design Guidelines. The preferred Concept Plan will be further analyzed to ensure full integration of both underground services and stormwater management.

5.1 CPT No. 4 and TAC No. 4

The preferred/refined Concept Plan and Design Guidelines will be presented and reviewed as part of CPT No. 4 and TAC No. 4. Comments will be received and gathered and adjustments will be made to the preferred Concept Plan and the Design Guidelines.

5.2 Attend POH No. 3

Once comments from CPT No. 4 and TAC No. 4 have been integrated, the Concept Plan and Design Guidelines will be presented as part during POH No. 3. This event will be advertised as the second mandatory public open house of Phase 2 of the Class EA, where alternatives will be presented to the general public to obtain their comments with respect to the final Concept Plan and Design Guidelines.

5.3 Preparation of a Draft Master Servicing Study

Based on the analyses completed as part of Task 4.2, a comprehensive Draft Master Servicing Study (MSS) document will be prepared that will synthesize the tasks conducted. This Draft MSS will identify infrastructure requirements and will be circulated to TAC members for their comments.

Barrhaven South Urban Expansion Area
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

TASK 6: THE BARRHAVEN SOUTH EXPANSION AREA COMMUNITY DESIGN PLAN

This task represents the finalization of the Community Design Plan, which will be a joint effort by the Consultant Team and members from the CPT. To support the CDP, the Mater Infrastructure Servicing Plan will be finalized based on both Task 5 and Task 6 findings. From JLR's perspective, the following tasks are envisioned:

6.1 Consolidate and Integrate Comments from CPT No. 4, TAC No. 4 and POH No. 3

Comments that have been received under Task 6 will be reviewed and consolidated. Once this review completed, the Concept Plan and Design Guidelines will be finalized. At that time, the CDP will be prepared. From a servicing perspective, the following will be completed:

- Finalize the Existing Conditions Report.
- Finalize the Design Guidelines.
- Finalize the Master Servicing Study (MSS). This document will:

  i) Summarize previously completed Reports in regard to infrastructure;
  ii) Confirm the capacity constraints of the existing infrastructure;
  iii) Identify proposed infrastructure for water, wastewater, storm and stormwater management; and
  iv) Identify servicing upgrades and associated financial implications.

6.2 CPT No. 5 and TAC No. 5

The CDP, Design Guidelines and other deliverables will be presented as part of CPT No. 5 and TAC No. 5. Comments will be received and gathered and adjustments will be made to CDP and other deliverables.

Barrhaven South Urban Expansion Area
Community Design Plan

Existing Conditions Report & Master Servicing Study
Terms of Reference (Revised March 23, 2016)

TASK 7: IMPLEMENTATION

Once the review completed by TAC, the CDP and supporting studies and deliverables will be finalized. The CDP will be implemented as an amendment to the Official Plan. A public meeting will be held at the Planning Committee to consider the CDP and implementing the OPA for City council approval.

EXECUTIVE SUMMARY

Minto Communities Inc. (Minto) and Mattamy Homes (Mattamy), herein referred to as the Owner, have retained a Consultant Team to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA) Community Design Plan (CDP), which will be implemented as an Amendment to the City of Ottawa Official Plan (OP). J.L. Richards & Associates Limited (JLR) has been retained to prepare a Master Servicing Study (MSS) to outline water, wastewater, storm, and stormwater management servicing strategies for the BSUEA. In advance of preparing the MSS, an Existing Conditions Report is required to evaluate and assess existing water resources and servicing infrastructure in and around the BSUEA, and to identify constraints and opportunities that will provide the baseline conditions of an Environmental Management Plan (EMP).

The BSUEA consists of 121 ha of land that is bounded by Cambrian Road to the north and Barnsdale Road to the south. The BSUEA is located immediately west of the current City of Ottawa Urban Boundary and approximately 360 m east of Borrisokane Road. The subject site is an undeveloped mix of former agricultural land and forested areas spread generally across the southern portion of the site. It contains two (2) ongoing aggregate extraction operations in the northern area of the site, extending west to the Borrisokane Road / Highway 416 corridor. Woodlots and pasture areas are adjacent to the site to the north, and recent urban development abuts the eastern boundary. The topography across the site has significant undulations and there is a knoll in the BSUEA located approximately 1 km north of Barnsdale Road. At the intersection of Borrisokane Road and Barnsdale Road, southwest of the site, there is an existing waterbody that appears to be man-made.

Based on interpreting the LiDAR data and the topographical survey compiled by Stantec (Geomatics), the BSUEA is tributary to three (3) sub-watersheds: the Jock River, Mud Creek via the Thomas Baxter Municipal Drain, and the Rideau River via the Hawkins Municipal Drain. The investigations completed by the Team's biologist did not identify any formal conveyance channels within the BSUEA. The absence of channels or formal watercourses was confirmed by the LiDAR data. The absence of such waterways is generally indicative of areas exhibiting particularly low surface runoff potential.

Catchment areas within the BSUEA have been delineated based on LiDAR data compiled on behalf of the City of Ottawa, as well as any surface infrastructure such as roads, which tend to

form a drainage path barrier, and culverts, where flow will concentrate into a point source. An understanding of the existing conditions in terms of capacity of the culverts and expected flow rates can be achieved from an accurate existing conditions hydrological model.

The SWMHYMO hydrological model for the BSUEA is a single event model for the purpose of estimating flood flows at the boundary control points of the site for storm events ranging from the 1:2 year and 1:100 year recurrence. The model was developed based on generally accepted standard hydrological parameters that fairly represent the land use, soil characteristics, types of flow paths, and topography. The simulated area included the BSUEA, as well as the lands up to the external boundary points: Cambrian Road, Borrisokane Road, and Barnsdale Road.

The SWMHYMO model results show relatively low flow rates at each of the culverts due to the high infiltration capability of the soils in the area and the low impervious ratio. In general, during larger and infrequent events, runoff will increase as the infiltration capability decreases due to saturation of the soils.

The water budget of a given area is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces, or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. The analysis of the water budget is often carried out to establish the baseline condition and assess any future changes in infiltration to subsurface water-bearing zones and, consequently, to surface runoff resulting from a significant land cover modification such as urbanization. It is also used to predict changes to the hydrological cycle that will result from urbanization of lands.

An understanding of the water budget within a given study area can be gained through the use of a continuous hydrological model. The PCSWMM software platform was used for this study, which included simplified groundwater and snowmelt modules that allowed the continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall, and snowmelt.

A long term simulation was carried out for the site and was based on 30 years of hourly precipitation and temperature. Based on the long-term simulation results, infiltration accounts for approximately 40% of the total annual precipitation of 844 mm, while surface runoff accounts for approximately 0% on a yearly average. Specifically, surface runoff accounts, on average, for 1 mm per year out of the total annual precipitation of 844 mm.

A review of the existing and planned infrastructure (sanitary sewers, watermains, storm sewers, and stormwater management facilities) in the vicinity of the BSUEA was undertaken to assess available servicing opportunities and constraints for the BSUEA.

The existing Greenbank Road trunk sanitary sewer was identified as the wastewater outlet for the existing Barrhaven South Community sanitary sewer system, which includes the Cambrian Road and River Mist Road trunk sanitary sewers. Based on the theoretical peak flow calculations, the existing Greenbank Road trunk sanitary sewer has sufficient capacity to accommodate the anticipated peak flows generated within the BSUEA. Furthermore, the total peak flow at downstream MH 522A (located at the intersection of Half Moon Bay Road and the existing Greenbank Road, immediately south of the Jock River) is anticipated to be less than 590 L/s. This was made a requirement by Stantec based on their 2013 Wastewater Collection System Assessment, which concluded that downstream wastewater infrastructure, including the South Nepean Collector and the West Rideau Collector, could accommodate a peak flow of 590 L/s from the Barrhaven South Community and the BSUEA, with no risk of surcharging and/or basement flooding. Measures to mitigate infiltration into the sanitary sewer system in the BSUEA are anticipated based on existing sewer and groundwater elevations.

Potable water will be provided to the BSUEA predominantly via extensions of existing and planned feedermains located along the existing Greenbank Road, Cambrian Road, River Mist Road, the future realigned Greenbank Road and a future Collector Road. Findings presented in the City of Ottawa Water Supply Optimization Study Report prepared by Delcan in 2008 recommended a Pressure Zone reconfiguration consisting of an expanded Zone 3C within areas previously identified as Pressure Zone BARR, including the Barrhaven South Community and the future BSUEA. Several water distribution projects were identified in the 2013 Infrastructure Master Plan to achieve the recommended zone reconfiguration. Certain growth areas, including the BSUEA, were identified as having low pressures notwithstanding the full zone reconfiguration. Hydraulic simulations showed that pressures less than 40 psi are anticipated along the future water distribution system servicing the elevated portion of the BSUEA. As a result, it is anticipated that a localized portion of the BSUEA may require a booster pumping station or, alternatively, oversized services combined with jet pumps. This condition, as well as water servicing specifics such as watermain looping and sizing of the feedermains for the BSUEA, will be addressed at the MSS stage by a hydraulic network analysis (HNA).

The existing Barrhaven South Community is currently serviced by two (2) stormwater management facilities (SWMFs) known as the Corrigan Pond and the Todd Pond. Three (3) additional SWMFs are planned to service the Barrhaven South Community in accordance with the Jock River Subwatershed Study and the Barrhaven South Master Servicing Study. These planned SMWFs are referred to as the Clarke Pond, Greenbank Pond and Cedarview Pond. Although all five (5) existing/planned SWMFs in Barrhaven South have residual water quality

volumes and have available residual capacity in their associated trunk infrastructure, all existing and planned storm sewer systems in Barrhaven South have relatively high hydraulic grade line elevations. The Corrigan and Todd Pond tributary areas also have major system ponding depths which are generally at or exceeding the maximum allowable depth of 0.35 m.

Given the limitations of the existing minor and major systems in the Barrhaven South Community, opportunities to provide stormwater servicing and stormwater management for the BSUEA via the three (3) planned SWMFs (Clarke, Cedarview and Greenbank) and their associated trunk storm sewers, will be reviewed in detail and evaluated as part of the BSUEA Master Servicing Study. Additionally, the servicing of a 5.6 ha parcel of land owned by Mattamy via the Todd Pond will be further reviewed. This parcel was previously allocated to the Todd Pond under an 'ultimate' scenario as part of the 2015 Clarke Pond Model Keeper Analysis completed by JFSA. Should a new wet pond facility be required, then the naturally low-lying topography at the southeastern corner of the Study Area would be the optimal location. This pond could provide both stormwater quantity and quality control for the BSUEA before outletting to the existing Greenbank Road trunk storm sewer.

EXISTING CONDITION REPORT

MINTO COMMUNITIES INC. & MATTAMY HOMES LTD.
BARRHAVEN SOUTH URBAN EXPANSION AREA

B1.0 INTRODUCTION

Minto Communities Inc. (Minto) and Mattamy Homes (Mattamy), herein referred to as the Owner, have retained a Consultant Team to prepare a series of comprehensive documents to support the Barrhaven South Urban Expansion Area (BSUEA) Community Design Plan (CDP), which will be implemented as an Amendment to the City of Ottawa Official Plan (OP). J.L. Richards & Associates Limited (JLR) has been retained to prepare a Master Servicing Study (MSS) to outline water, wastewater, storm, and stormwater management servicing strategies for the BSUEA. In advance of preparing the MSS, an Existing Conditions Report is required to evaluate and assess existing water resources and servicing infrastructure in and around the BSUEA, and to identify constraints and opportunities that will provide the baseline conditions of an Environmental Management Plan (EMP).

B2.0 STUDY AREA

B2.1 Location

The BSUEA consists of 121 ha of land that is bounded by Cambrian Road to the north and Barnsdale Road to the south. The BSUEA is located immediately west of the current City of Ottawa Urban Boundary and approximately 360 m east of Borrisokane Road, as shown in **Figure 2-1**.

The BSUEA CDP area shown in **Figure 2-1** represents the latest boundary limits. Although there has been no change to the overall CDP area of 121 ha, prior to these limits being established under a provisional agreement with the City of Ottawa, the boundary limit along the existing Greenbank Road was further west, approximately following an extension of River Mist Road. A corresponding area on the west side was then included, following the boundary of property PIN 045921577. The new CDP boundary, as presented in **Figure 2-1**, will allow for a more logical development pattern, with improved phasing opportunities and more efficient connection to surrounding development.

B2.2 Characteristics

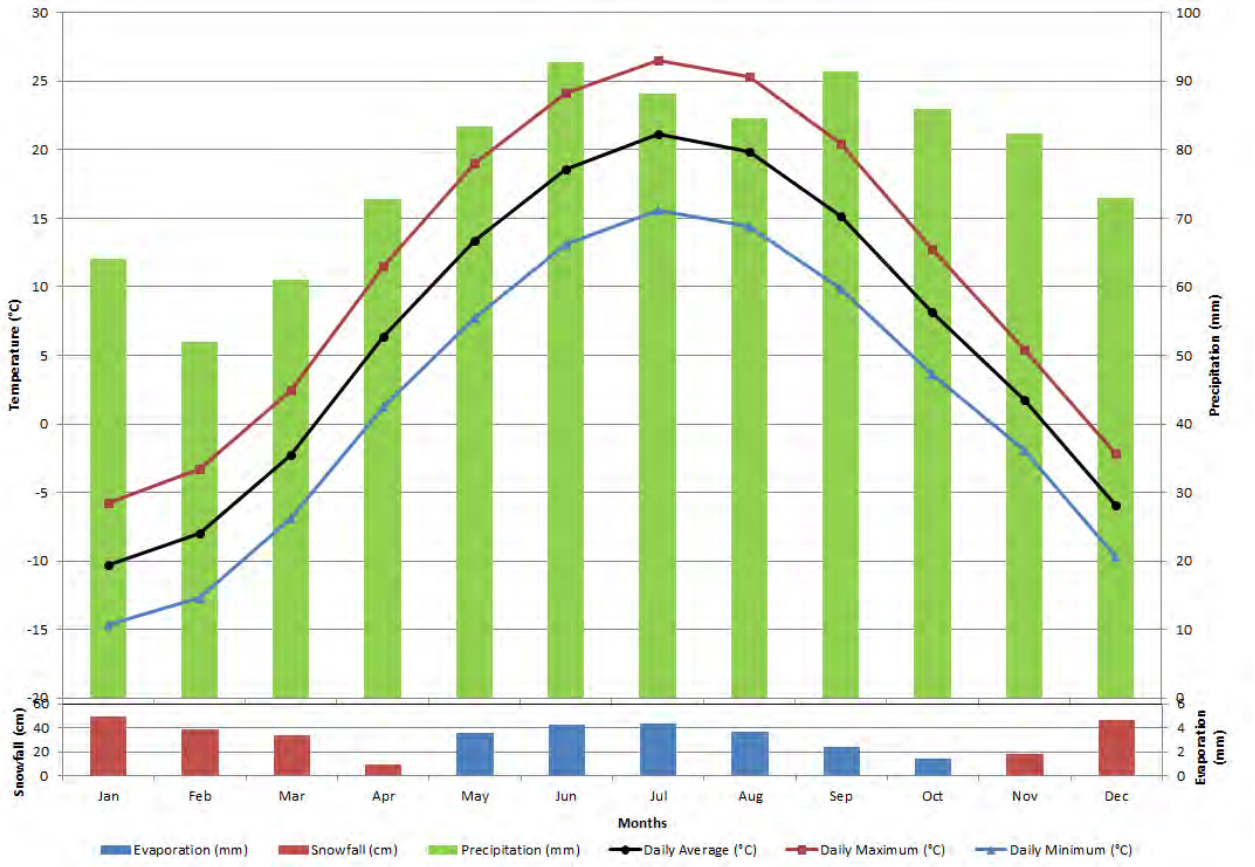
The subject site is an undeveloped mix of former agricultural land and forested areas. It contains two (2) ongoing aggregate extraction operations (Brazeau and Drummond). The southern portion of the site is generally former agricultural land, with some woodlot areas. The aggregate extraction operations are in the northern area of the site, extending west to the Borrisokane Road / Highway 416 corridor. Woodlots and pasture areas are adjacent to the site to the north, and recent urban development abuts the eastern boundary. The topography across the site has significant undulations, with elevations generally varying from approximately 111 m at the peak to approximately 99 m at the lowest point. However, there is also a knoll in the BSUEA south of the Brazeau lands where the existing ground is above 111 m. At the intersection of Borrisokane Road and Barnsdale Road, southwest of the site, there is an existing waterbody that appears to be man-made.

B2.3 Climate

Environment Canada collects meteorological data at two (2) weather stations within the vicinity of the study area: the Ottawa CDA at the Experimental Farm (16 km to the northeast) and the Ottawa MacDonald Cartier International Airport (10 km to the northeast). The averages of the data collected at these two (2) stations provide some information on the climate expected in the study area (**Figure 2-2**).

The average temperature for the BSUEA varies between about -10°C in the winter and over 20°C in the summer. The daily maximum and minimum averages vary between 3.7 and 5.5 degrees from the average, with the greatest difference observed in the summer months. Evaporation is high in the summer, and negligible in the winter. Snowfall is highest during the December/January period. Generally, precipitation volumes are higher in the summer months, although the season variation is not as pronounced compared to temperature: the seasonal differences are usually no more than 40 mm and for three quarters (75%) of the year the variation in precipitation is no more than 20 mm.

Figure 2-2: Environment Canada, Ottawa Climate Normals



B3.0 BACKGROUND DOCUMENTS

There are a large number of documents and reports that have been prepared regarding the lands covered by the BSUEA and/or lands surrounding the site. The documents include subwatershed studies of the Jock River, covering the areas north of the site, and Mud Creek, covering the south of the site, and servicing strategies for the surrounding urban development lands northeast of the site.

The Reports listed below have been summarized in **Appendix 'B1'**. The Reports can be classified in the following four (4) categories:

1. Reports covering a large geographical area, including the site:

- *Jock River Reach One Subwatershed Study Final Report*. Stantec Consulting Ltd. (June 2007). City of Ottawa.
- *Jock River Subwatershed Report 2010: A report on the environmental condition of the Jock River*. Rideau Valley Conservation Authority. (April 2011).

- *Mud Creek Subwatershed Study*. City of Ottawa, Planning and Growth Management. (October 2015).
- *Mud Creek Subwatershed Existing Conditions Report Phase I Summary*. City of Ottawa Land Use and Natural Systems Policy Group. 2011.
- *Jock River Reach 2 & Mud Creek Subwatershed Study Existing Conditions Report (Final)*. Marshall Macklin Monaghan Limited and Water & Earth Sciences Associates. (May 2009). City of Ottawa.
- *Lower Rideau River Subwatershed Report 2012: A report on the environmental condition of the Lower Rideau River*. Rideau Valley Conservation Authority. (February 2013).
- *Lower Rideau Watershed Strategy Final Report*. Aquafor Beech / Robinson Consultants Inc. (September 2005). Rideau Valley Conservation Authority.
- *Barrhaven South Official Plan Amendment Submission*. David McManus Engineering Ltd. (August 2008). Minto Communities Inc.
- *Aggregate Resource Designated Lands Study, 3882 Barnsdale Road, Ottawa, Ontario*. Paterson Group Inc. (February 2012). Minto Communities Inc.

2. Site Servicing Strategies for adjacent urban development sites:

- *Barrhaven South Master Servicing Study Final Report*. Stantec Consulting Ltd. (June 2007). City of Ottawa.
- *2013 Infrastructure Master Plan Wastewater Collection System Assessment.* Stantec Consulting Ltd. (September 17, 2013). City of Ottawa.
- *City of Ottawa 2013 Water Master Plan.* Stantec Consulting Ltd. (September 20, 2013). City of Ottawa.
- *Infrastructure Master Plan*. City of Ottawa. (November 2013).
- *Barrhaven South Master Servicing Study Addendum Draft Report*. Stantec Consulting Ltd. (November 2014). City of Ottawa.
- *Barrhaven MSS Draft Addendum* – Revised Potable Water and Sanitary Servicing Analysis for the BSUEA. Stantec Consulting Ltd. (October 19, 2016).
- *Manotick Master Drainage Plan Phase I*. A.J. Robinson and Associates Inc. (October 1993). Township of Rideau.
- *Manotick Master Drainage Plan Phase II*. Robinson Consultants Inc. (February 1996). Township of Rideau.

3. Surrounding Infrastructure Reports:

- *Corrigan Stormwater Management Facility Stormwater Management Report and Design Brief*. IBI Group (July 2010). McNeil Farm Limited.

- Stormwater Management Barrhaven South. IBI Group (October 2014). Minto Communities Inc.
- Letter Report (June 9, 2015) entitled "Respond to the City of Ottawa Comment – Corrigan SWM Facility" addressed to J.L. Richards & Associates Limited.

- *Todd Pond and Clarke Pond Model Keeper Update Analysis / Update of Half Moon Bay South Subdivision Plan. Letter to David Schaeffer Engineering Limited*. J.F. Sabourin and Associates Inc. July 25, 2013.
- *Todd Pond Model Keeper Analysis Re-Assessment of Existing System Capacity*. J.F. Sabourin and Associates Limited. (April 2015). City of Ottawa.

B4.0 GEOLOGY AND PHYSIOGRAPHY

A geotechnical investigation was carried out by Paterson Group Inc. (Paterson) to assess general subsoil and groundwater conditions within the BSUEA and to provide geotechnical recommendations for the design of municipal services associated with the proposed development. A field program, consisting of 30 boreholes and 125 test pits, was carried out in November and December 2015. A supplemental program followed in July 2016 with 6 boreholes and 36 permeameter tests. The boreholes/test pits were advanced to depths ranging from 2.6 m to 9.8 m below existing ground surface. The test hole locations for the current investigation were distributed in a manner to provide general coverage of the BSUEA and adjacent properties. Previous investigations had been carried out in 2003 and 2011, which consisted of 27 test pits that were advanced to

depths ranging from 2.7 m to 7.0 m. Detailed findings and recommendations have been compiled in the Report entitled "Geotechnical Investigation Proposed Barrhaven South Urban Expansion Area - Community Design Plan, Paterson Group Inc., January 26, 2017. The general findings of the above-noted Report are summarized in Sections B4.1 to B4.3 (below).

B4.1 Surficial Geology

Mapping reviewed by the geology team indicated that overburden soils at the site consist of primarily glaciofluvial deposits to the north with reworked glaciofluvial sand deposits to the west and southwest. The results of the sub-surface investigations were generally consistent with the mapping. Overburden thicknesses were found to be around 10 m to 17 m across the site. The overburden generally consisted of topsoil over silty sand to a sandy silt deposit.

B4.2 Bedrock

Based on digital geological mapping produced by Natural Resources Canada, sourced from the Geological Survey of Canada, the bedrock in this area consists of dolomite of the Oxford formation with an overburden drift thickness of 15 m to 25 m depth. Bedrock was not encountered in any of the boreholes or test pits ordered across the site.

B4.3 Aquifer Systems and Groundwater

Aquifer systems are geological material which permits the movement of groundwater under hydraulic gradients. The overburden soils at the site are, according to the geotechnical report, relatively deep and consist of moderate to high hydraulic conductivities. Three (3) aquifer systems are present across the site: the underlying bedrock aquifer, the deeper overburden aquifer, and a shallower overburden aquifer.

Monitoring wells were installed in the overburden to assess the hydrogeological characteristics across the site. The results of the testing suggest that the permeable overburden aquifer is acting as a recharge area for the esker and bedrock aquifers. The saturated conditions are considered by the geotechnical team to be representative of the long term water table and will vary in level seasonally and with precipitation events.

Groundwater levels were found to be generally highest in the centre of the site with groundwater elevations of up to 101 m above sea level. However, the analysis by Paterson found that, when compared to potential grading on the site, groundwater levels could be within 3.5 to 4.5 m of the surface at the southeastern corner of the site around the existing Greenbank Road / Barnsdale Road intersection.

B5.0 SITE HYDROLOGY AND HYDRAULICS

B5.1 General

Based on interpreting the LiDAR data and the topographical survey compiled by Stantec (Geomatics), the BSUEA is tributary to three (3) sub-watersheds: the Jock River, Mud Creek via the Thomas Baxter Municipal Drain, and the Rideau River via the Hawkins Municipal Drain. The area tributary to the above-noted sub-watersheds has been depicted in Figure 5-1. Based on the study area limits, approximately 99 ha is tributary to the Jock River while areas of approximately 11 ha and approximately 13 ha are tributary to Mud Creek and Rideau River, respectively. It is noted that although the Spence Branch of the Thomas Baxter Municipal Drain (shown at the bottom of Figure 5-2) is mapped by the City as Municipal Drain, it was not found during site observations. All flows appear to go to the Dynes Branch west of Borrisokane Road.

The investigations completed by the Team's biologist did not identify any formal conveyance channels within the BSUEA. The absence of channels or formal watercourses was confirmed by the LiDAR data. The absence of such waterways is generally indicative of areas exhibiting particularly low surface runoff potential. As a result, runoff generated from the site is carried as overland sheet flow to the natural low points at the culvert outlet locations.

B5.2 Water Crossings

A total of thirteen culvert crossings were inventoried, which can be grouped into the following two (2) categories:

1. Boundary: There are five (5) culvert crossings acting as boundary control points to the area being modelled. Two (2) are located along Cambrian Road to the north of the BSUEA and three (3) are along Barnsdale Road to the south of the BSUEA. These five (5) crossings form the downstream boundary of the modeled area, where overland sheet flow forms a concentrated point flow external to the site;
2. Internal to the model: There are eight (8) culvert crossings that are internal to the area being modelled. These crossings currently provide conveyance across access routes to property and farmland along Borrisokane Road and Barnsdale Road.

The inventoried crossings have been summarized in **Table 5-1** and **Table 5-2**, below, while **Figure 5-2** depicts the location of the culvert crossings along with the general site hydrology. It should be noted that none of the inventoried water crossings are within the BSUEA limits, although BDR-C5 is on the boundary of the BSUEA.

BDR-C6	On Barnsdale Road, 60 m west of the existing Greenbank Road	Circ. CSP	400

It should be noted that culvert CR-C2 was not included as part of the topographical survey and size is currently unknown.

The 2014 Barrhaven South Master Servicing Study Draft Addendum (Draft 2014 BSMSSA) prepared by Stantec, notes that water crossing CR-C1 is to be replaced with storm sewers when the Clarke West Municipal Drain is enclosed as part of the adjacent development and the Clarke Stormwater Management Facility is constructed. The Draft 2014 BSMSSA also indicated that culvert CR-C2 is to be maintained, and will accommodate flows from the existing catchment area south of Cambrian Road up to the 1:100 year event. Should future development occur south of the woodlot draining to CR-C2, grading and servicing from the future development area in the vicinity of the woodlot should be developed to maximize overland sheet flow drainage (not channelized) towards the woodlot.

Table 5-2: Inventory of Model Water Crossings (Internal)

Culvert ID	Location	Type	Size (mm)

B5.3 Watershed Delineation

Catchment areas within the BSUEA have been delineated based on LiDAR data compiled on behalf of the City of Ottawa, as well as any surface infrastructure such as roads, which tend to form a drainage path barrier, and culverts, where flow will concentrate into a point source. The delineated catchment areas are split by the three (3) watershed areas: Jock River to the north of the site, Mud Creek to the south and the Rideau River watershed to the east. The catchment areas are summarized in Table 5-3 and are shown in Figure 5-2.

Table 5-3: Subcatchment Summary

B5.4 Hydrological Modeling

Since the 1980s, hydrological models have become the principal tool used to calculate flood flows under extreme conditions and assess flooding impacts along water bodies and within urban areas.

An understanding of the existing conditions, in terms of capacity of the culverts and expected flow rates, can be achieved from an accurate existing conditions hydrological model. To simulate the hydrological response of a given area, a hydrologic model should ideally be calibrated to actual monitored flows to ensure a true representation of the physical characteristics of the catchment area during the recorded storm events. For this project, surface flows were not monitored within the limits of the BSUEA and, consequently, the hydrological model was not calibrated. The model was developed based on generally accepted standard hydrological parameters that fairly represent the land use, soil characteristics, types of flow paths, and topography.

The SWMHYMO hydrological model for the BSUEA is a single event model for the purpose of estimating flood flows at the boundary control points of the site for storm events ranging from the 1:2 year and 1:100 year recurrence. The simulated area included the BSUEA, as well as the lands up to the external boundary points: Cambrian Road, Borrisokane Road and Barnsdale Road. Figure 5-2 shows the extent of the simulated areas and the drainage areas delineated for the project.

B5.4.1 Aggregate Extraction Pits

Parts of the BSUEA continue to be used for aggregate extraction. These existing aggregate extraction pits act as large basins and will contain runoff on site until the trapped stormwater is lost to either infiltration or evaporation, or is pumped off site. This runoff condition is the result of man-made activities: originally, runoff would have left the site and contributed to flows at the boundary culvert. As a result, the pre-development condition model for the site was developed assuming the pre-extraction condition based on topography as per the plans submitted to the Ministry of Natural Resources and Forestry (MNRF), where available, or as a constantly sloped surface to the surrounding natural ground level where the original topography is unknown.

B5.5 Model Parameters

The site was modeled using the SCS Curve Number (CN) methodology to predict runoff. The CN number is selected based on the soil types in the area and the land cover, which in this case is predominately rural in nature with either agricultural or woodlot classifications. The site consists of ‘unimproved lands’, which consist of lands that are undeveloped open space with no current use. This classification was also used for the quarry areas. Land uses for the model area are shown in Figure 5-3, while a summary of the hydrological parameters is shown in Table 5-4.

Table 5-4 - Model Parameter Summary

Drainage Area ID	Area (ha)	CN*	Initial Abstraction (mm)	Time to Peak (hrs)	% Impervious
A1	18.6	42	23.3	0.41	
A2	35.4	49	18.3	0.59	
A3	12.7	67	8.7	0.43	
A4	14.0	37	27.4	0.33	
A5	12.7	50	17.6	0.39	
A6	11.7	53	15.6	0.27	
A7	15.5	51	16.9	0.72	
A8	42.3	53	15.6	0.74	
A9	5.1	50	17.6	0.25	
A10	5.5	55	14.4	0.27	
A11	15.2	55	14.4	1.27	
A12	60.0	51	16.9	0.95	
A13	24.6	52	16.2	0.5	
A14	22.4	40	25.3	1.5	
A15	3.5	61	11.1	0.39	
A16	2.9	37	27.4	0.24	
A17	9.8	44	21.5	0.42	
A18	0.5	66	9.4	See Note 1	26%
A19	1.0	72	10.4	See Note 1	20%
A20	4.8	49	18.3	0.32	
A21	1.5	57	13.2	See Note 1	27%

Note 1: Areas A18, A19 and A21 are simulated using the Standhyd command and therefore do not use the Time to Peak parameter. The impervious ratio parameters for these drainage areas are shown.

The soil types in the area are predominately soils with high infiltration and low runoff potential, even when saturated. The Hydrologic Soil Group (HSG) Types A and AB dominate the site across nearly three quarters (75%) of the modeled area. HSG Type C, which are sandy clay loam soils with low infiltration rates when thoroughly saturated, and have a corresponding relatively higher runoff, occurs across approximately 1% of the site. Two percent (2%) of the area is impervious due to roads or dwellings while mid-range soils make up the remainder of the modeled area. Soil types by geotechnical description are depicted in Figure 5-4.

The model schematic is contained in **Appendix 'B2'** which also includes a detailed description of all the model parameters, including Time to Peak, Initial Abstraction, etc.

B5.5.1 Storm Distribution

The hydrological response of the BSUEA and abutting lands was simulated under a 6 hour, 12 hour and 24 hour SCS Type II storm distribution. The SCS Type II storm distribution was developed by the American Soil Conservation Service and is generally used for estimating flows in rural areas. The critical storm event under pre-development conditions, with the highest peak runoff, was found to occur under the 12 hour SCS Type II storm distribution.

B5.6 Modeling Results

The pre-development SWMHYMO simulation results, predicting flows at each of the culverts for the critical storm event, are shown in Table 5-5, below. The estimated capacity and level of service of each culvert is also provided. The details of culvert CR-C2, crossing Cambrian Road at Borrisokane Road, could not be obtained in the field due to obstructions and/or structural failure. Hence, the capacity and level of service at this culvert could not be confirmed.

Table 5-5: Hydrological Simulation Results at Culvert Locations (12 hour SCS Type II storm)

Culvert ID	Flow (m^3/s) at culvert location for return period (recurrence)						Estimated Culvert Capacity (m^3/s)	Estimated Level of Service (years)
	1:2 yr	1:5 yr	1:10 yr	1:25 yr	1:50 yr	1:100 yr		
CR-C1	0.3	0.7	1.0	1.6	2.0	2.5	5.5	1:100
CR-C2	0.2	0.4	0.7	1.0	1.3	1.6	N/A	N/A
CVR-C1	0.1	0.3	0.5	0.8	1.0	1.3	0.4	1:5
CVR-C2	0.0	0.1	0.1	0.2	0.2	0.3	0.2	1:25
CVR-C3	0.0	0.1	0.2	0.2	0.3	0.4	0.3	1:50
CVR-C4	0.2	0.4	0.6	0.9	1.1	1.4	2.6	1:100
BDR-C1	0.0	0.0	0.1	0.1	0.1	0.2	0.2	1:100
BDR-C2	0.0	0.1	0.1	0.1	0.2	0.2	0.2	1:50
BDR-C3	0.1	0.1	0.1	0.2	0.2	0.3	0.5	1:100
BDR-C4	0.2	0.4	0.6	0.9	1.2	1.5	2.6	1:100
BDR-C5	0.0	0.0	0.0	0.0	0.0	0.1	0.3	1:100
BDR-C6	0.0	0.0	0.1	0.1	0.2	0.2	0.2	1:100
BDR-C7	0.1	0.1	0.1	0.2	0.3	0.4	0.3	1:50
Total Flow to Thomas Baxter Municipal Drain	0.2	0.5	0.7	1.1	1.3	1.6	N/A	N/A

The SWMHYMO model results show relatively low flow rates at each of the culverts, due to the high infiltration capability of the soils in the area and the low impervious ratio. In general, during larger and infrequent events, runoff will increase as the infiltration capability decreases due to saturation of the soils.

The culverts crossing the main boundary roads to the site, CR-C1, CR-C2, BDR-C4, BDR-C5 and BDR-C6, have high estimated levels of service (in excess of 1:100 years), with the exception of two (2) culverts on Barnsdale Road and the culvert on Cambrian Road, which is unrecorded. Since these roads are classified as arterial or collector roads, they would be expected to have a higher level of service compared to the culverts internal to the site or under access roads south of Barnsdale Road.

B5.6.1 Hydraulics and Floodplain Mapping

There are no well-defined watercourses on the site which are suitable to hydraulic analysis or to prepare floodplain mapping. Flow conveyance for the majority of the site occurs by means of overland sheet flow, and flow in small, intermittent channels. The floodplain of the Jock River subwatershed extends close to the site but remains within the northwestern quadrant of the Cambrian Road / Borrisokane Road intersection (**Figure 5-1**). The floodplains of the Rideau River and Mud Creek do not extend to the site.

B6.0 WATER BUDGET

The water budget of a given area is often studied by hydrologists and hydrogeologists to better understand the movement of water through its various stages. Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to the groundwater system, evaporation from water surfaces, or transpiration from vegetation, completing the natural cycle back into atmospheric moisture and precipitation. The analysis of the water budget is often carried out to establish the baseline condition and assess any future changes in infiltration to subsurface water-bearing zones and, consequently, to surface runoff resulting from a significant land cover modification such as urbanization. It is also used to predict changes to the hydrological cycle that will result from urbanization of lands. Figure 6-1 summarizes graphically the natural hydrological cycle describing the continuous movement of water on, above, and below the surface.

In simple terms, the general water budget assesses the change in water storage resulting from the difference in water inputs and outputs for a given area or watershed. To estimate the water budget, the following simplified equation is used:

$$P = ET + SW + GW + \Delta S$$

Where:

- P is precipitation;
- ET is evapotranspiration;
- SW is surface runoff;
- GW is groundwater; and
- ΔS is the difference in water storage.

As a fundamental requirement, the water budget developed for the existing conditions will be used as the baseline condition when assessing the effectiveness of any stormwater management (SWM) strategies under the post-development condition. Future SWM strategies should adhere to the recent provincial guidance from the MOECC in their publication entitled “Expectation interpretation bulletin, February 2015”, as well as relevant provincial policy statement. One of the objectives of the upcoming Master Servicing Study will be to develop a storm servicing strategy that will incorporate mitigation measures to minimize the water deficit in an effort to offset the potential impact of urbanization.

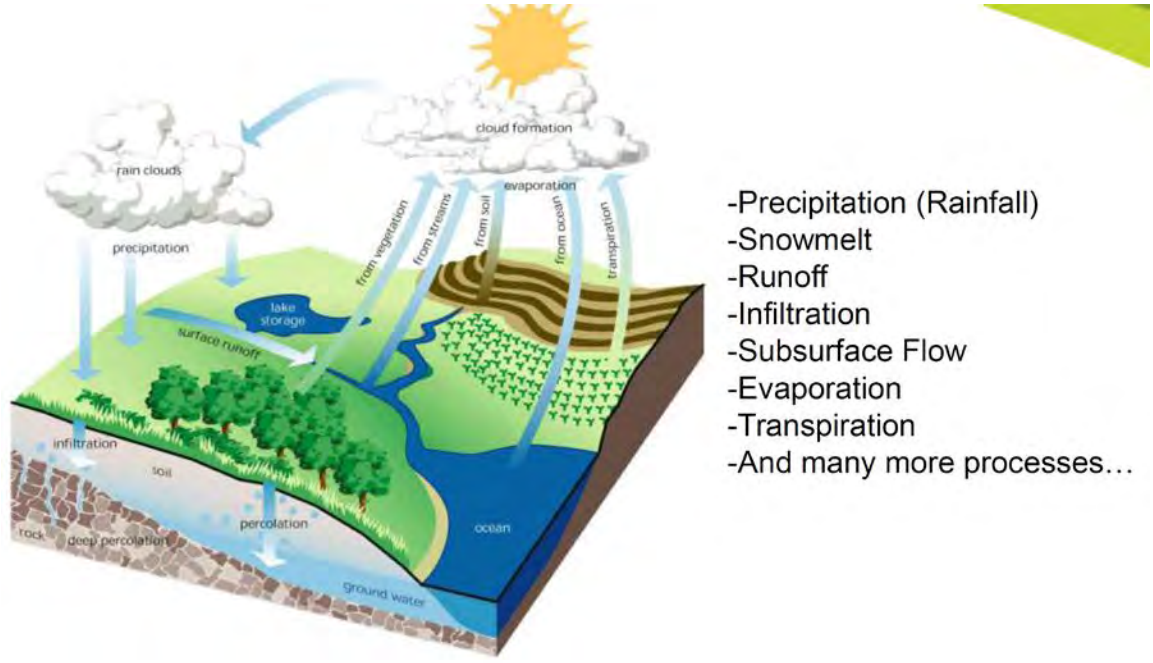

Figure 6-1: Water Budget Cycle

B6.1 Continuous Simulation Modeling

An understanding of the water budget within a given study area can be gained through the use of a continuous hydrological model. The Toronto and Region Conservation

Authority (TRCA), in their publication entitled “Stormwater Management Criteria, August 2012”, recommend the use of a continuous model such as QUALHYMO or PCSWMM.

The PCSWMM model to be used for this study includes simplified groundwater and snowmelt modules that allow the continuous simulation of the water budget, including the elements of evapotranspiration, the groundwater table (lower saturated zone), snowfall, and snowmelt. Due to its capabilities and versatility, the PCSWMM modeling tool will also be used to assess the impact of development and effectiveness of the proposed Low Impact Development (LID).

B6.1.1 Infiltration Parameters

Saturated field hydraulic conductivity of the surficial soils for the southern and eastern parts of the study area was measured on-site by Paterson. The saturated field hydraulic conductivity (Kfs) blocks ranged from $2.7x10^{-7}$ m/s to less than $8x10^{-5}$ m/s. The Ontario Ministry of Municipal Affairs and Housing (MMAH) Building Code Supplementary Standard SB-6 (2012) provides guidance on converting saturated field hydraulic conductivity (Kfs) to infiltration rate via the Percolation Time (an extract of this Supplementary Standard is included in **Appendix 'B3'**). For permeable gravel sand mixtures, which have saturated field hydraulic conductivities in the range of $1x10^{-4}$ to $1x10^{-6}$ m/s, the percolation rate is in the range of 12 to 4 mins/cm, which is equivalent to 50 to 150 mm/hr. Therefore, the range of infiltration rates across the extent tested by Paterson varies between 49.8 mm/hr and 106.8 mm/hr.

In the PCSWMM model, subcatchments were delineated based on the saturated field hydraulic conductivity blocks and maximum, median, and minimum infiltration values selected for each block. Field testing was not available to determine the Saturated Infiltration coefficient for the Horton infiltration method (minimum or final infiltration rate). Consequently, the values of the final infiltration capacity were estimated based on the initial infiltration capacity and the soil type. **Table 6-1,** below, summarizes the various ranges of saturated field hydraulic conductivities and their corresponding range of maximum infiltration rates as well as the selected final infiltration coefficient used in the water budget model.

It should be noted that a decay constant, k, of 4.14 hr^{-1}, was used in the PCSWMM model to mimic the decreasing infiltration capacity of the soil over time during wet weather events.

Table 6-1: Horton Coefficients for Water Budget Model

Range of Kfs (m/s)	Max Range Infiltration Values (mm/hr)	Estimated Soil Groupings (based on infiltration values)[1]	Range of Expected Final Infiltration Values (mm/hr)[1]	Selected Final Infiltration Coefficient (mm/hr)
$2.7x10^{-7}$ – $9.9x10^{-7}$	49.8 – 50.0	Moist Loam Soils	3.8 - 7.6	4
$1.0x10^{-6}$ – $9.9x10^{-6}$	50.0 – 53.2	Moist Loam soils	3.8 - 7.6	4 - 7
$1.0x10^{-5}$ – $8.0x10^{-5}$	53.2 – 106.8	Moist to Dry Sandy Soils	7.6 – 11.4	7 - 11

B6.1.2 Precipitation and Evaporation

The continuous simulation model was run using precipitation data from the Environment Canada weather stations at Ottawa Macdonald-Cartier International Airport and the Experimental Farm in Ottawa (approximately 10 km and 15 km from the BSUEA respectively). In excess of 30 years of hourly data, between January 1, 1960 and October 31, 1990, was used to undertake the water budget analysis. The average annual rainfall during this period was 844 mm, while maximum and minimum daily temperatures from the same weather stations and time period were also used.

The model undertakes evaporation calculations based on average monthly rates of evaporation (as reported by Environment Canada, refer to Section **B2.3**) and from the available standing water that is "trapped" in natural depressions within the subcatchment surfaces as a result of the initial abstraction depth.

B6.1.3 Groundwater

PCSWMM analyzes groundwater flow for each subcatchment independently. It represents the subsurface region beneath a subcatchment as an unsaturated upper zone that lies above a lower saturated zone. The elevation of the lower saturated zone, the water table, varies in time depending on the rates of flow into and out of the lower saturated zone. The flow to the lower saturated zone is controlled by percolation, which is dictated by the soil characteristics. The upper unsaturated zone receives water via infiltration from surface runoff. Evapotranspiration occurs from the upper unsaturated zone; it can also occur from the lower saturated zone, depending on root depth. If the water table, or elevation of the lower saturated zone, reaches the surface level then all the soil is saturated and infiltration will no longer occur.

[1] Akan, A. O., *Urban Stormwater Hydrology: A Guide to Engineering Calculations.* Lancaster: Technomic Publishing Co., Inc., 1993 (extract contained in **Appendix 'B3'**).

For the purposes of modelling the water budget's existing condition, subcatchments were delineated by each hydrologic soils group (HSG) within the BSUEA. Properties currently operating as aggregate pits were delineated as separate subcatchments. The soil parameters associated with each HSG are detailed in **Appendix 'B3'**.

B6.1.4 Snowmelt

Snowmelt is an additional mechanism by which runoff may be generated in a continuous simulation model. The current PCSWMM software platform utilizes the Canadian SWMM snowmelt routines with extensions for long term continuous modelling.

Snowfall rates are determined directly from hourly precipitation data by using a pre-set temperature: snowfall will occur when the temperature is below the pre-set point and rainfall when above. Snowmelt is handled differently by PCSWMM, depending on the occurrence of rainfall. During rain on snowmelt events, the model takes into account the rainfall intensity and the air temperature as well as the saturation vapour pressure. When snowmelt occurs without any rainfall, the snowmelt is linearly proportional to the air temperature, which varies with the user supplied melt coefficients. The parameters used in the snowmelt module are detailed in **Appendix 'B3'**.

For the existing condition model it has been assumed that all snow occurs on pervious land cover and there is no snow removal.

B6.1.5 Continuous Simulation Results

A long term simulation was carried out for the maximum, minimum, and median of each of the infiltration ranges of each block. The summary of the simulation results is given in **Table 6-2**, below, which has been grouped based on the above noted ranges of infiltration. These results show that there is no significant variation within the range of values for each set of infiltration values. This is expected, as the peak rainfall events over a 30-year simulation period are generally lower than the infiltration rates (ranging between ±50 mm/hr and ±105 mm/hr) within the frequent event ranges and are, therefore, not affected. Only the infrequent large peak rainfall events will be affected by the change in infiltration within the range of values.

Table 6-2: Comparison of Results with Range of Infiltration Values

Annual Water Budget Components	Minimum Infiltration	Median Infiltration	Maximum Infiltration
Precipitation (mm/year)	844	844	844
Evapotranspiration (mm/year)	506	506	506
Infiltration (mm/year)	336	337	338
Surface Runoff (mm/year)	2	1	1

Since there is negligible variability in the simulation results shown above, only the median infiltration values will be considered going forward with the water budget analysis. Based on the medium infiltration, the continuous simulation results have been summarized for each of the three (3) subwatersheds as shown in **Table 6-3**, below.

Table 6-3: Water Budget Continuous Simulation Results

Annual Water Budget Components	Annual Average Depth (mm)				Budget %
	To Jock River	To Mud Creek	To Rideau River	Area Weighted Total	
Precipitation	844	844	844	844	100%
Evapotranspiration	506	506	506	506	60%
Infiltration	338	336	336	337	40%
Surface Runoff	1	2	2	1	0%

Based on the above long-term simulation results, infiltration accounts for approximately 40% of the total annual precipitation of 844 mm, while surface runoff accounts for approximately 0% on a yearly average. Specifically, surface runoff accounts, on average, for 1 mm per year out of the total annual precipitation of 844 mm, representing approximately 0.1%.

Although the average annual total depth of runoff is virtually non-existent percentage wise, the model computed surface flows when precipitation depths were encountered that exceeded a 1:5 year recurrence or when peak intensities were greater than a 1:2 year recurrence. Based on the review of the 30-year simulation results, a peak flow of 3.27 m^3/s was computed as the largest flow by the model. This peak flow was generated from the overall BSUEA and sheet flow draining towards the three (3) sub-watershed outlets; a peak flow of 2.44 m^3/s was computed as being directed to the Jock River as summarized in **Table 6-4**, below.

The event resulting in the largest peak runoff occurred on August 4, 1988 and is one of the historical storms listed in the City of Ottawa Sewer Design Guidelines to be simulated to assess the performance of drainage systems. However, the large events

are infrequent in nature; the peak flow generated on August 4, 1988 was experienced once during the 30-year simulation. **Table 6-4**, below, summarizes the five (5) greatest and smallest peak flow events generated by the model with the associated rainfall depth and peak intensity as well as its corresponding frequency.

Table 6-4: Top Five Largest and Smallest Peak Flow Events

Date	Peak Runoff to Jock (m^3/s)	Peak Runoff to Mud (m^3/s)	Peak Runoff to Rideau (m^3/s)	Storm Duration (hrs)	Peak Rainfall Intensity (mm/hr)	Equivalent Return Period	Total Rainfall Volume (mm)	Equivalent Return Period
August 4, 1988	2.44	0.40	0.43	4	37.4	10 year	77.0	100 year
August 8, 1973	0.42	0.15	0.16	7	30.2	5 year	60.5	10 year
June 16, 1981	0.35	0.14	0.15	2	36.9	10 year	38.3	5 year
June 11, 1973	0.34	0.14	0.15	3	33	5 year	42.4	5 year
August 8, 1973	0.31	0.07	0.10	8	30.2	5 year	60.5	10 year
June 11, 1976	0.02	0.01	0.02	2	24.6	2 year	24.9	2 year
Sept. 12, 1963	0.01	0.01	0.01	8	10.2	< 2 year	52.4	5 year
Sept. 11, 1986	0.01	0.01	0.01	14	14	< 2 year	42.9	5 year
July 1, 1979	0	0	0	5	14.0	< 2 year	26.3	< 2 year

Note: shaded columns above highlight the computed flows during two (2) historical storms.

The following conclusions can be drawn from the statistics summarized in the above table:

- The largest event, from a volumetric perspective, occurred on August 4, 1988 with a recorded volume of 77 mm over four (4) hours, which, compared to the City of Ottawa IDF curve, has a frequency greater than a 1:100 year; and
- From a peak intensity perspective, the August 4, 1988 event was the largest with a recorded peak intensity of 37 mm/hr, which, compared to the City of Ottawa IDF curve, has a frequency of 1:10 year.

Three (3) events were recorded with a peak intensity of between 36 and 37 mm/hour, which, given that this is approximately a 1:10 year return period event, is true to the statistics. Only two (2) of these recorded any runoff as the total volume of runoff was insufficient to trigger flow.

In terms of rainfall volume, none of the events over the 30-year simulation period were greater than a 1:10 year event, other than the one which resulted in the largest peak flow

and one other 24-hour period, which did receive more rainfall than the 1:100 year volume; however, the peak intensity was 20 mm/hr, less than a 1:2 year event. Due to the low peak intensity, this other 1:100 year event did not trigger any runoff flows.

The City of Ottawa has three (3) historical events that are used to assess how a system would function under historical extreme events. The 1988 event triggered the largest runoff flow from the BSUEA; however, the 1979 event did not result in any runoff. The simulation uses hourly rainfall data that averages the intensities within the hour period and creates an average peak, which will be of less significance when compared to any peak intensities identified in the 5-minute data.

A preliminary high level scenario of a potential future water budget was simulated for a development having a total imperviousness of 65%, of which 58.5% is Directly Connected Impervious area (i.e., 90% of the total imperviousness was assumed to be directly connected) without any Best Management Practices to promote infiltration. The results indicate that the percentage of infiltration will reduce from 40% (existing condition) to 28% (post-development without BMPs) of the overall annual water budget. Simulation results have also shown reductions in evapotranspiration as a result of the decrease in vegetation which, in turn, generates increases in surface runoff. Consequently, stormwater management measures promoting infiltration will be necessary to meet the target of maintaining pre-development infiltration levels.

B7.0 EXISTING INFRASTRUCTURE AND SERVICING SUMMARY

B7.1 Trunk Wastewater Servicing

In 2007, as part of the Barrhaven South Master Servicing Study (BSMSS), Stantec modelled the existing South Nepean Collector (SNC) and West Rideau Collector (WRC) trunk sewers to determine whether they could both accommodate peak flows from new development in Barrhaven South, up to the current Urban Boundary. Their analysis consisted of the following two (2) scenarios:

- Peak flows for existing development were established based on monitored flow data while peak flows for future development in Barrhaven South were calculated based on theoretical flow generation parameters given in the 2004 City of Ottawa Sewer Design Guidelines[2]; and

[2] As the BSMSS was completed in 2007, the 2004 Sewer Design Guidelines were current at that time. The Design Guidelines were updated in 2012; however, the 2007 BSMSS still references the 2004 version.

- Peak flows for both existing and future development were calculated based on the theoretical flow generation parameters given in the 2004 Ottawa Sewer Design Guidelines.

Modeling results showed that under Scenario 1, the existing SNC and WRC could accommodate the additional flow generated from Barrhaven South; however, under Scenario 2, the SNC and WRC showed risk of surcharging and basement flooding at certain locations.

In September 2013, Stantec completed a City-wide Wastewater Collection System Assessment to identify areas in need of wastewater collection system upgrades to accommodate projected growth to 2031 and 2060. This assessment served as the basis of the wastewater component of the City's 2013 Infrastructure Master Plan (IMP). To complete the assessment, Stantec developed a hydrodynamic model using PCSWMM that included all existing and planned (approved) sanitary trunk sewers (i.e., greater than 450 mm in diameter), pumping stations, and associated wastewater infrastructure in the City. Simulations were carried out based on monitored flow data obtained from 31 locations throughout the City under dry weather conditions and wet weather flow parameters established from two (2) historical rainfall events and one synthetic storm event (the 1:100 year storm). Flow generation for future development areas was based on average flow rates consistent with the 2012 Design Guidelines. Based on the simulation results, the 2013 Stantec Assessment did not identify any growth-related areas at risk nor recommend system upgrades in Barrhaven South under both the 2031 and 2060 planned growth horizons. Consequently, no wastewater projects were identified within Barrhaven South as part of the November 2013 IMP.

In 2014, Stantec issued a draft addendum to their 2007 BSMSS. In this addendum, herein referred to as the Draft 2014 BSMSSA, the peak flow projected in 2007 was re-calculated to account for actual peak flow values from developments that had been approved and/or constructed since the completion of the 2007 BSMSS. These developments included Mattamy's Half Moon Bay and Half Moon Bay South and Tamarack Homes' The Meadows at Half Moon Bay. The Draft 2014 BSMSSA also considered the design parameters prescribed in the 2012 Design Guidelines for calculating both existing and future development peak flows in Barrhaven South. The total peak sanitary flow re-calculated for the Barrhaven South Community as part of the Draft 2014 BSMSSA was found to be significantly less than the peak flow allocated for Barrhaven South as part of the 2013 Wastewater Collection System Assessment by Stantec. Consequently, as indicated in the Draft 2014 BSMSSA, Stantec concluded that downstream wastewater infrastructure, including the SNC and WRC, could accommodate the peak flows from the Barrhaven South Community with no risk of surcharging or basement flooding. **Table 7-1** provides the peak flows calculated for

Barrhaven South, up to the current Urban Boundary, as part of the three (3) aforementioned studies. These peak flows were calculated at downstream sanitary maintenance hole 522A, located at the intersection of the existing Greenbank Road and Half Moon Bay Road, immediately south of the Jock River.

Table 7-1: Total Sanitary Peak Flow for Barrhaven South

Study	Barrhaven South Peak Flow (l/s)
2007 BSMSS	388
2013 IMP Model	590
Draft 2014 BSMSSA	412

B7.1.1 Existing Sanitary Sewers

Wastewater servicing for existing development in Barrhaven South was designed in general conformance with the 2007 BSMSS and the Draft 2014 BSMSSA (refer to the Sanitary Servicing Plan prepared by Stantec in **Appendix 'B4'**). The southerly portion of the existing Barrhaven South Community is serviced by the following three (3) main trunk sanitary sewers as shown on **Figure 7-1**:

- Existing Greenbank Road Trunk Sanitary Sewer
  This sewer extends approximately 2 km south of the Jock River up to the current Urban Boundary. At its upstream end, at the Urban Boundary, this sewer is 600 mm in diameter, with a 0.25% slope, an obvert elevation of 91.77 m and is 6.7 m below existing ground.

- Cambrian Road Trunk Sanitary Sewer
  This sewer extends approximately 1 km west of the existing Greenbank Road up to the future realigned Greenbank Road. At its upstream end, at the future realigned Greenbank Road, this sewer is 500 mm in diameter, with a 0.20% slope, an obvert elevation of 89.53 m and is 4.1 m below existing ground.

- River Mist Road Trunk Sanitary Sewer
  This sewer extends approximately 1.7 km south of Cambrian Road to the southern limit of the current Urban Boundary (within Minto's Quinn's Pointe subdivision). At its upstream end, at the Urban Boundary, this sewer is 200 mm in diameter, with a 0.32% slope, an obvert elevation of 100.44 m and is 3.3 m below existing ground. As its downstream end, at Cambrian Road, this sewer is 375 mm in diameter.

DRAWING NO.:

FIGURE 7-1

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\Civil\26610 C Figure 7.dwg

PLOT DATE: December 19, 2016 2:01:27 PM

The Cambrian Road and River Mist Road trunk sanitary sewers convey wastewater to the existing Greenbank Road trunk sanitary sewer, which outlets to the SNC and, ultimately, to the WRC.

A review of the trunk sanitary sewers in Barrhaven South was undertaken to evaluate whether there is available capacity in the existing sanitary sewer system to service additional lands outside the current Urban Boundary. Design sheets for the three (3) existing trunk sanitary sewers listed above were reviewed to identify the limiting pipe reach in terms of available residual capacity. It should be noted that the review was based on theoretical peak flow calculations and not monitored flow data. Based on the theoretical peak flows presented in the Draft 2014 BSMSSA Sanitary Sewer Design Sheet prepared by Stantec (a copy of which is provided in **Appendix 'B4'**), the limiting residual capacity in each trunk sanitary sewer is shown in Table 7-2, below.

Table 7-2: Available Residual Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Limiting Pipe Reach	Residual Capacity (L/s)
Existing Greenbank Road	MH 45 to MH45A	295.4
Cambrian Road	MH13A to MH15A	51.4
River Mist Road	MH 102A to MH17A	17.8

Furthermore, as part of the detailed design of the Quinn's Pointe subdivision, tributary areas were reassigned from the existing Greenbank Road trunk sanitary sewer to the River Mist Road trunk sanitary sewer due to a change in the alignment of River Mist Road that was implemented following the issuance of the Draft 2014 BSMSSA. As a result, a higher peak flow is conveyed to the River Mist Road trunk sanitary sewer in comparison to the allocated flow in the Draft 2014 BSMSSA. Therefore, the available residual capacity in the River Mist Road trunk sanitary sewer is slightly less than that indicated in Table 7-2 above, as summarized in **Table 7-3**.

Table 7-3: River Mist Road Trunk Sanitary Sewer Available Residual Capacity

Quinn's Pointe Allocation per Draft 2014 BSMSSA	10.40 L/s
Peak flow per Quinn's Pointe detailed design	13.77 L/s
Difference	3.37 L/s additional
River Mist Residual Capacity per Table 7-2	17.8 L/s
River Mist Revised Residual Capacity	**14.4 L/s**

It should be noted that the critical pipe reach on the existing Greenbank Road trunk sanitary sewer is located downstream of the Cambrian Road and River Mist Road trunk sanitary sewers (refer to the Sanitary Servicing Plan in **Appendix 'B4'**). Should future

development require the use of the entire theoretical residual capacities of the River Mist Road and Cambrian Road trunk sanitary sewers (i.e., 14.4 L/s and 51.4 L/s, respectively), then the allowable peak flow that could be conveyed by the existing Greenbank Road trunk sanitary sewer downstream of Cambrian Road is 229.6 L/s (i.e., 295.4 – 51.4 – 14.4 = 229.6 L/s).

B7.1.2 Planned Trunk Sanitary Sewers

There are also trunk sanitary sewers in Barrhaven South within the current Urban Boundary that have yet to be constructed, as shown in the Draft 2014 BSMSSA. These planned trunk sanitary sewers are identified by dashed lines in **Figure 7-1** and are described as follows:

- Future Cambrian Road Trunk Sanitary Sewer
  This sewer is to extend approximately 400 m west of the existing Cambrian Road trunk sanitary sewer to the future Collector Roadway located approximately 500 m east of Borrisokane Road. As per the Draft 2014 BSMSSA, this sewer is proposed to be 375 mm in diameter, with a 0.40% slope and an upstream obvert elevation of 91.38 m at the future Collector, which is 2.1 m below existing ground.

- Future Collector Road Trunk Sanitary Sewer
  This sewer is to extend approximately 550 m south of Cambrian Road along a future Collector located between the future realigned Greenbank Road and Borrisokane Road. As per the Draft 2014 BSMSSA, this sewer is to be 300 mm in diameter, with a 0.75% slope and an upstream obvert elevation of 95.00 m, which is 5.0 m below existing ground.

- Future Realigned Greenbank Road Trunk Sanitary Sewer
  This sewer is to extend approximately 800 m south of Cambrian Road along the future realigned Greenbank Road. As per the Draft 2014 BSMSSA, this sewer is proposed to have an upstream diameter of 250 mm, with a 1.30% slope and an obvert elevation of 96.10 m north of Dundonald Drive, which is 6.9 m below existing ground.

Similar to the existing trunk sanitary sewers, these planned (future) trunk sanitary sewers in Barrhaven South will convey wastewater to the existing Greenbank Road trunk sanitary sewer which ultimately outlets to the SNC.

B7.2 Water Servicing

B7.2.1 Existing Conditions

The existing Barrhaven South Community is part of the City's Pressure Zone BARR which is fed from Pressure Zone 2W via the following two (2) source transmission mains:

1. The Woodroffe Avenue 1200 mm diameter watermain (from Baseline Road to Fallowfield Road); and
2. The Fallowfield Road 762 mm diameter watermain.

The Barrhaven Reservoir, located off of Fallowfield Road, acts as balancing storage for Zone 2W and feeds the Barrhaven Pumping Station (BPS), which boosts water to the Pressure Zone BARR.

B7.2.2 Future Zone Reconfiguration

Findings presented in the City of Ottawa Water Supply Optimization Study Report prepared by Delcan in 2008, and more recently in the Draft 2014 BSMSSA, showed that a reconfiguration of pressure zones within the South Urban Community (which includes the Barrhaven South Community) would eliminate the need for a new pumping station, minimize system fragmentation (dead-ends), and generally improve system reliability and operation. This recommended zone reconfiguration consists of an expanded Zone 3C within areas originally identified as Pressure Zone BARR, including the Barrhaven South Community and the future BSUEA. The City elected to move forward with the zone reconfiguration and has, therefore, identified several water distribution projects in their 2013 IMP that are required to achieve the recommended zone reconfiguration and meet future growth and reliability needs up to the 2031 planning horizon within the South Urban Community. These IMP projects are as follows:

- Barrhaven Reservoir Pumping Station Upgrade;
- Fallowfield Road Watermain Upgrade (from the Barrhaven Reservoir to Borrisokane Road);
- Barrhaven Pumping Station Upgrade;
- Barrhaven-3C Feedermain (from Foxfield at Holitman to Via Chianti Grove); and
- Existing Greenbank Road Watermain (from north of Jockvale to south of the Jock River).

Refer to extracts from the 2013 IMP provided in **Appendix 'B5'** for details on the above-noted projects.

It should be noted that as part of the City of Ottawa 2013 Water Master Plan analyses, Stantec has highlighted a particular constraint in terms of providing water servicing for the BSUEA. Hydraulic simulation results for growth areas within the South Urban Community up to the 2031 planning horizon have shown that low pressures (i.e., less than 40 psi) are anticipated along the future water distribution system that will be servicing the elevated portion of the BSUEA (refer to Figure 5-5: Residual Pressure Distribution – SUC – 2031 provided in **Appendix 'B5')**. As a result, a new booster pumping station and oversized services or jet pumps are anticipated to be required in order to provide adequate water servicing within the BSUEA.

B7.2.3 Existing Watermains and Operating Pressures

Water servicing for existing development in the Barrhaven South Community was developed in general conformance with the 2007 BSMSS and the more recent Draft 2014 BSMSSA (refer to the Water Servicing Plan prepared by Stantec in **Appendix 'B5'**). Potable water is supplied to the southerly portion of the existing Barrhaven South Community by the following existing feedermains, as shown in **Figure 7-2**:

- Existing Greenbank Road 406 mm Diameter Feedermain
  This feedermain extends approximately 2 km south of the Jock River up to the southerly limit of the current Urban Boundary.

- Existing Cambrian Road 406 mm Diameter Feedermain
  This feedermain extends from the existing Greenbank Road to the future realigned Greenbank Road.

- Existing River Mist Road 305 mm Diameter Feedermain
  This feedermain extends the entire length of River Mist Road from River Run Avenue up to the southerly limit of the current Urban Boundary. The actual alignment of this feedermain was slightly revised from the Draft 2014 BSMSSA, which showed a 305 mm diameter feedermain along Alex Polowin Avenue, from Kilbirnie Drive up to the southerly limit of the Urban Boundary (refer to **Figure 7-2** and the Draft 2014 BSMSSA Water Servicing Plan provided in **Appendix 'B5'**).

B7.2.4 Future Watermains and Operating Pressures

As part of the long-term infrastructure needs, there will also be a requirement to extend existing feedermains that are planned but are yet to be constructed within the current Urban Boundary. These future planned watermains, which have been identified in the Draft 2014 BSMSSA, include the following and are shown as dashed lines on **Figure 7-2**.

FIGURE 7-2

File Location: R:\26000\26610 - Barrhaven Expansion - Minto Brazeau Mattamy\JLR DWG\Civil\26610 C Figure 7.dwg

PLOT DATE: December 19, 2016 2:02:06 PM

- Future 305 mm diameter feedermain on the future realigned Greenbank Road
  This feedermain is to extend by approximately 2 km south of Cambrian Road, past the current Urban Boundary and about 500 m east to River Mist Road to complete a 305 mm diameter watermain loop.

- Future 406 mm diameter feedermain on Cambrian Road
  This feedermain is to extend from the future realigned Greenbank Road to Borrisokane Road.

- Future 305 mm diameter feedermain on future Collector Road
  This feedermain, located along the future Collector Road between Borrisokane Road and the future realigned Greenbank Road, is to extend approximately 550 m south of Cambrian Road to the current Urban Boundary and approximately 430 m east to the future realigned Greenbank Road feedermain to complete a system loop.

In terms of the existing operating pressures and hydraulic grade lines (HGL) in Pressure Zone BARR under domestic and fire flow conditions, the following information was extracted from the Draft 2014 BSMSSA:

- The HGL in Pressure Zone BARR is dependent on the water levels in the Moodie Drive Tank, the pump discharge pressure, and the system head losses. When those elements are factored in, the HGL is found to typically vary from a minimum of 147 m to a maximum of 160 m under fire flow and domestic demands.
- Ground elevations in Pressure Zone BARR range between a minimum elevation of 84 m and a maximum elevation of 117 m. The range in Barrhaven South is between a minimum of 83 m and a maximum of 110 m, while the ground elevations in the BSUEA range between 99 m and 111 m.
- During basic day demand and under the maximum operating HGL of 160 m, pressures in Barrhaven South are expected to range between 489 kPa (71 psi) and 751 kPa (109 psi), assuming no system head loss. As noted in Section 5.2.1 of the Draft 2014 BSMSSA, low lying areas will experience pressures greater than 80 psi (552 kPa).
- During peak hour and under the minimum operating HGL of 147 m, pressures in Barrhaven South are expected to range between 365 kPa (53 psi) and 627 kPa (91 psi), assuming no system head losses.

B7.2.5 Future Operating Pressures in the BSUEA

Water servicing needs in the BSUEA will be investigated and evaluated as part of the upcoming Master Servicing Study (MSS) for the BSUEA. The existing and planned trunk feedermains, as depicted on **Figure 7-2**, will serve as the backbone of the future trunks

within the BSUEA. The Draft 2014 BSMSSA has to be finalized before the BSUEA MSS can begin. The Draft 2014 BSMSSA will evaluate the performance of the water distribution system at a preliminary level, to determine whether the system can support the urbanization of the BSUEA, referred to as Area 7. This work will be finalized early in 2017, in advance of adopting the Community Design Plan. Results from this undertaking will be extracted and included in this section of the Existing Condition Report when made available.

As previously noted, Barrhaven South, as well as the BSUEA, will be serviced from an expanded Zone 3C by future watermain extensions. As per the Draft 2014 BSMSSA, potable water will originate from the Barrhaven Pumping Station where a constant 147 m discharge HGL will be maintained under the various range of demands. Table 7-4 summarizes the operating pressures in Barrhaven South and the BSUEA (information extracted from the Draft 2014 BSMSSA).

Table 7-4: Residual Pressure during Basic and Peak Hour Demands

Area	Zone	Basic Day Maximum Pressure kPa (psi)	Peak Hour Minimum Pressure kPa (psi)
Barrhaven South	3C	372 (54) - 607 (88)	296 (43) - 503 (73)

B7.3 BSUEA Stormwater Servicing and Stormwater Management

A preferred stormwater management (SWM) strategy for Barrhaven South up to the current Urban Boundary was first identified in the Jock River Reach One Subwatershed Study prepared by Stantec in June 2007. This preferred SWM strategy included five (5) wet pond facilities that would provide quality control (to an MOE enhanced level of protection, 80% suspended solids removal) before discharging to the Jock River. The 2007 Jock River Reach One Subwatershed Study served as the basis for the 2007 BSMSS, also prepared by Stantec, which outlined tributary areas and trunk storm sewers to convey stormwater to the five (5) wet pond facilities. These five (5) facilities were strategically located south of the Jock River and referred to as Corrigan, Todd, Clarke, Borrisokane and Greenbank (refer to **Appendix 'B6'** for a copy of the 2007 BSMSS Conceptual SWM Storm Servicing Plan, Drawing ST1, prepared by Stantec).

A Draft Addendum to the 2007 BSMSS was subsequently issued by Stantec in 2014 to address changes in SWM criteria established in the 2012 Design Guidelines and associated Technical Bulletins. The Draft 2014 BSMSSA also incorporated the detailed designs of the Corrigan and Todd Ponds and their tributary infrastructure, which were completed since the issuance of the 2007 BSMSS.

The following provides an overview of existing and planned stormwater infrastructure for both minor and major systems in Barrhaven South that is associated with each of the five (5) designated wet pond facilities. The minor storm system is comprised of street gutters, catch basins, inlet control devices, junction chambers, and storm sewers and conveys stormwater during frequent storm events (i.e., generally up to the 1:5 year storm event). The major system is comprised of swales, roadway sags, streets, etc. and generally conveys stormwater flows overland, up to the 1:100 year storm event, when flows are in excess of the minor system capacity.

B7.3.1 Corrigan Pond

In 2008, the detailed design of the Corrigan Pond was carried out by the IBI Group (IBI). Construction of the Pond was completed in 2010. The Corrigan Pond is located south of the Jock River, east of the existing Greenbank Road, and currently services a tributary area of approximately 148 ha within the eastern portion of the existing Barrhaven South Community, as shown on the Drainage Schematic (dated June 2015) prepared by IBI, and provided in **Appendix 'B6'**.

Minor System

Existing trunk storm sewers that outlet to the Corrigan Pond include the following, as shown in **Figure 7-3** and on the Drainage Schematic prepared by IBI provided in **Appendix 'B6'**:

- Existing Tucana Way Trunk Storm Sewer
  This sewer extends approximately 450 m south of the Corrigan Pond to Cambrian Road.

- Existing Cambrian Road Trunk Storm Sewer
  This sewer extends approximately 400 m west of Tucana Way to the existing Greenbank Road.

- Existing Greenbank Road Trunk Storm Sewer
  This sewer extends from Cambrian Road to approximately 1.7 km south of Cambrian Road, at the southern limit of the current Urban Boundary. At its upstream end, at the Urban Boundary, this sewer is 1800 mm in diameter, with a 0.16% slope, an obvert elevation of 94.07 m and is about 3.9 m below existing ground.

It should also be noted that there is another storm sewer along the existing Greenbank Road, north of Cambrian Road. This storm sewer serves as an overflow; diverting flows of approximately 6.8 m^3/s of stormwater directly to the Jock River during the 1:100 year storm event (refer to IBI's Drainage Schematic provided in **Appendix 'B6'**).

In terms of hydraulic grade line (HGL) along the existing trunk storm sewers, simulation results provided in IBI's 2014 Stormwater Management Barrhaven South Report indicate that although certain portions of the trunk storm sewers experience surcharging under the 1:100 year storm event (SCS Type II), the minimum required freeboard of 30 cm to the underside of footing (USF) of each unit is still achieved throughout the system. The minimum freeboard in the system is 0.32 m at MH 104B on the existing Greenbank Road.

In terms of water quality analysis, the latest June 9, 2015 letter issued by IBI confirmed that the existing Corrigan Pond exceeds the required water quality volume to achieve an MOE enhanced level of protection for the current 147.5 ha tributary area, which is inclusive of the most recent detailed design of Minto's Quinn's Pointe subdivision. The existing Corrigan Pond has 1700 m^3 of residual permanent pool storage and 100m^3 of residual extended detention storage.

Major System

Major system flows generated from existing development located south of Cambrian Road and east of the existing Greenbank Road are tributary to the Corrigan Pond. Since overland flow is not permitted to cross arterial roadways (i.e., Cambrian Road and the existing Greenbank Road) as per the Design Guidelines, major system flows generated within these lands are conveyed overland to designated storage areas where they are released, at a restricted flow rate, back into the minor system of the Corrigan Pond. These storage areas consist of a parking lot and park which are identified as Areas B5D and B6, respectively, on the Dual Drainage Cascading Flow Figure prepared by IBI and provided in **Appendix 'B6'**. This Figure also shows that major system flows generated from existing development located to the north of Cambrian Road and to the east of the existing Greenbank Road outlet directly to the Jock River.

Major system flows generated in Minto's Quinn's Pointe subdivision are also ultimately conveyed to the Corrigan Pond. Since the subdivision is located to the west of the existing Greenbank Road, major system flows are first conveyed and captured by a dry pond located at the southern limit of Quinn's Pointe where they are released, at a restricted rate, to the Corrigan Pond minor system. As per the July 2015 Site Servicing Report for Quinn's Pointe prepared by JLR, the maximum major system street ponding depth in the subdivision is 35 cm (static and dynamic), in accordance with City Design Guidelines.

With the exception of the Quinn's Pointe subdivision, the remainder of the major system flow generated from lands to the west of the existing Greenbank Road is conveyed to the Todd Pond.

B7.3.2 Todd Pond

The detailed design of the Todd Pond was carried out by J.F. Sabourin and Associates Inc. (JFSA) in 2008. It is located in the northeast quadrant of the Cambrian Road and River Mist Road intersection. It is noted that the existing Todd Pond configuration is slightly different than the proposed configuration outlined in the 2007 BSMSS since the existing pond is not bisected by Cambrian Road.

The Todd Pond currently services a tributary area of approximately 141 ha within the existing central portion of Barrhaven South. This tributary area includes the Half Moon Bay, The Meadows and Half Moon Bay South subdivisions as shown in the Overall Drainage Area to Todd Pond (Figure 2) prepared by JFSA, and included in **Appendix 'B6'**. The latest model keeper analysis for the Todd Pond, completed by JFSA in April 2015, confirmed that the existing Todd Pond exceeds the MOECC's water quality volume requirement to achieve an enhanced level of protection for its tributary area based on the detailed designs of developments in Barrhaven South. The Todd Pond has approximately 6900 m^3 of residual permanent pool storage.

Minor System

Existing trunk storm sewers servicing the southerly portion of the Todd Pond tributary area include the following, as shown on **Figure 7-3**:

- Existing River Mist Road Trunk Storm Sewer
  This sewer extends from the Todd Pond to approximately 1.2 km south of Cambrian Road.

- Existing Cambrian Road Trunk Storm Sewer
  This sewer extends from the Todd Pond to approximately 500 m west of River Mist Road.

For the existing Half Moon Bay and a portion of The Meadows and Half Moon Bay South subdivisions, HGL analyses of the existing storm sewers tributary to the Todd Pond were completed at detailed design and approved based on the 1:100 year 3-hour Chicago design storm only. Based on this design storm, these developments meet the City's minimum freeboard requirement of 30 cm between the HGL and the USF, as indicated in the April 2015 Todd Pond Model Keeper Analysis.

The HGL analyses for these existing/approved developments did not, however, consider the 1:100 year 24-hour SCS Type II design storm and 1:100 year + 20% climate change stress test. As a result, under these two (2) designs storms, the minimum 30 cm freeboard is not always achieved, as noted by JFSA in the 2015 Todd Pond Model Keeper Analysis. However, the HGL was identified by JFSA as always below the finished basement floor elevation of existing units, as shown in Figure I-1: Lots with less than 30 cm freeboard, prepared by JFSA and provided in **Appendix 'B6'**. As indicated on Figure I-1, the minimum freeboard was found to be 23 cm above USF during the 1:100 year 24-hour SCS Type II design storm. Although the 30 cm freeboard for HGL and USF criterion was not respected, JFSA concluded that the existing units were not at risk of basement flooding.

As part of the latest Todd Pond Model Keeper Analysis completed in April 2015, JFSA analysed an 'ultimate' tributary area to the Todd Pond, which included minor system flows from 5.6 ha of future development lands, owned by Mattamy, located outside of the current Urban Boundary and within the BSUEA (refer to Figure 3, prepared by JFSA and provided in **Appendix 'B6',** for ultimate tributary area boundary). It is noted that the HGL analysis results summarized on Figure I-1, prepared by JFSA, include this ultimate drainage area and therefore existing basements would not be at risk of flooding with the addition of the 5.6 ha area. JFSA concluded that, in order for the Todd Pond to accommodate minor system flows from the additional 5.6 ha of future development area (based on an imperviousness of 56%), the current 30 m long Todd Pond outlet weir would have to be extended to a length of 48 m.

Major System

Major system flows generated from existing subdivisions west of the existing Greenbank Road including Half Moon Bay, The Meadows and Half Moon Bay South are conveyed to the Todd Pond. Since the Todd Pond is located immediately north of Cambrian Road, which is an arterial roadway, all major overland flow up to the 1:100 year storm was designed to be captured by the minor system just south of Cambrian Road so that the flows are conveyed to the Todd Pond without crossing Cambrian Road overland. Furthermore, the minor system also captures major system flow up to the 1:100 year storm at the northern property limit of Half Moon Bay South and The Meadows so that overland flow is not conveyed between subdivisions during the 1:100 year storm, with the exception of 2.33 m^3/s conveyed from Half Moon Bay South at Penant Avenue to Regatta Avenue in The Meadows.

As noted in the JFSA 2015 Todd Pond Model Keeper Analysis, some of the existing road sag storage areas exceed the maximum allowable ponding depth of 30 cm (static and dynamic for new developed areas) during the 1:100 year storm, in contravention of the 2012 Design Guidelines. These road sags are identified on Figure I-2, prepared by JFSA

and provided in **Appendix 'B6'.** It is also noted that some of these road storage areas exceed a maximum ponding depth of 35 cm (static and dynamic) during the 1:100 year storm, in contravention of more recent guidelines, specifically, Technical Bulletin PIEDTB-2016-01.

Major system flows generated by Minto's Quinn's Pointe subdivision were originally identified to flow overland to the Half Moon Bay South subdivision and, ultimately, to the Todd Pond as per the 2007 BSMSS. Quinn's Pointe was allocated a total allowable major overland flow rate of 1.2 m³/s (divided into 0.9 m³/s and 0.3 m³/s at two (2) outlets). However, the 2014 Stormwater Management Report for Quinn's Pointe (formerly referred to as Barrhaven South Phase 1), prepared by IBI, showed that the proposed Quinn's Pointe development would exceed the allowable major system release rate of 1.2 m³/s to Half Moon Bay South. Consequently, an alternative SWM solution was developed where the 1.2 m³/s major system release rate to existing development was not required. This solution consisted of a dry pond, located at the low-lying southeastern corner of Quinn's Pointe, to which major system flows were conveyed and released back into the minor system. This SWM approach was implemented in JLR's detailed design for the subdivision, the construction of which has recently been completed.

The 5.6 ha of future development lands owned by Mattamy outside of the current Urban Boundary within the BSUEA were also accounted for as part of the major overland flows tributary to the Todd Pond. In JFSA's 2015 Todd Pond Model Keeper Analysis, both minor and major system flows generated from these future lands were allocated under the 'ultimate' scenario – refer to Figure 3, prepared by JFSA and provided in **Appendix 'B6'**. It is noted that the ponding depths shown on Figure I-2, prepared by JFSA, consider this ultimate drainage area. The analysis concluded that in order for the Todd Pond to be able to accommodate minor and major flows from these future lands, the Todd Pond outlet weir would have to be extended from 30 m to 48 m in length.

B7.3.3 Clarke Pond

As per the Draft 2014 BSMSSA, the Clarke Pond is proposed to be located approximately 250 m north of Cambrian Road and approximately 780 m west of River Mist Road. It is intended to service the southwestern portion of Barrhaven South up to the southern limit of the current Urban Boundary. The analysis and sizing of the Clarke Pond was initiated by JFSA in 2011 and has since been updated in 2013 to incorporate the detailed designs of developments in Barrhaven South that were completed since 2011.

Minor System

The following planned trunk storm sewers were identified in the Draft 2014 BSMSSA to convey stormwater generated from the southern portion of Barrhaven South (up to the current Urban Boundary) to the Clarke Pond, as shown in **Figure 7-3**:

- Future Realigned Greenbank Road Trunk Storm Sewer
  This sewer is to extend approximately 1.2 km south of the Clarke Pond to the limit of the current Urban Boundary. At its upstream end, at the Urban Boundary, it is anticipated that, as per the Draft 2014 BSMSSA, this sewer will have a diameter of 825 mm, a slope of 1.0%, an obvert elevation of 102.95 (invert of 102.11), and a cover depth of 5.1 m.

- Future Collector Road Trunk Storm Sewer
  This sewer is to extend from the Clarke Pond to approximately 350 m south of Cambrian Road. At its upstream end, it is anticipated that, as per the Draft 2014 BSMSSA, this sewer will have a diameter of 1200 mm, a slope of 0.55%, an obvert elevation of 92.20 m (invert of 90.98), and a cover depth of 5.8 m.

- Future Cambrian Road Trunk Storm Sewer
  Planned sewers on Cambrian Road are to convey stormwater either towards the planned future realigned Greenbank Road trunk sewer or to the planned future Collector Road trunk storm sewer.

Due to the grade raise constraints within the northern portion of Barrhaven South and the normal water level in the Jock River, it is anticipated that the majority of the planned storm sewers outletting to the Clarke Pond will be partially submerged, as shown on the Draft 2014 BSMSSA Drainage Area Plan provided in **Appendix 'B6'**. Maintenance solutions to minimize the accumulation of sediments within the submerged sewers are to be addressed at detailed design, as indicated in the Draft 2014 BSMSSA.

Major System

Areas bounded by Cambrian Road and the future realigned Greenbank Road are to provide on-site storage to contain major system flow up to the 1:100 year storm such that the flows do not cross these arterials. Major system flows generated from lands located north of Cambrian Road and west of the future realigned Greenbank Road are to be conveyed directly to the Clarke Pond, as shown on the Draft 2014 BSMSSA Drainage Area Plan prepared by Stantec and provided in **Appendix 'B6'**.

B7.3.4 Cedarview Pond

Cedarview Pond is a future SWM facility that is proposed to be located immediately south of the Jock River, west of the future realigned Greenbank Road as per the Draft

2014 BSMSSA. The detailed design of the Pond has not yet been initiated; however, it is intended to serve as an outlet for planned minor system storm sewers servicing the northwestern portion of Barrhaven South (refer to Cedarview Pond Drainage Area Plan prepared by Stantec, provided in **Appendix 'B6'**). Furthermore, most major system flow generated within the Cedarview Pond tributary area is intended to be conveyed overland directly to the Jock River as shown on Stantec's Cedarview Drainage Plan in **Appendix 'B5'**.

B7.3.5 Greenbank Pond

Greenbank Pond is a future SWM facility that is proposed immediately south of the future realigned Greenbank Road and southwest of the Jock River as per the Draft 2014 BSMSSA. The detailed design of the Pond has been initiated by David Schaeffer Engineering Limited (DSEL) as part of Mattamy's Half Moon Bay Phase 7 Subdivision. The Greenbank Pond is to serve as an outlet for planned minor system storm sewers servicing the central northern portion of Barrhaven South - refer to the Draft 2014 BSMSSA Greenbank Pond Drainage Area Plan prepared by Stantec and provided in **Appendix 'B6'**. Furthermore, major system flow for tributary lands located south of the future realigned Greenbank Road is intended to be conveyed overland to the Greenbank Pond, while major system flow to the north of the future realigned Greenbank Road is intended to be conveyed overland directly to the Jock River, as per the Greenbank Pond Drainage Plan provided in **Appendix 'B6'**.

B8.0 OPPORTUNITIES AND CONSTRAINTS

B8.1 Drainage Network

The review of LiDAR data and the Headwater Drainage Feature Assessment concluded that there were no waterways or watercourses within the limits of the BSUEA. The lack of waterways is generally indicative of the low frequency in the flow generation potential for a given area. Based on the measured saturated hydraulic conductivities and corresponding calculated infiltration rates, the surface water flow component accounts for 1.2% of the total annual precipitation depth of 844 mm. As part of storm servicing, some constraints such as modification to drainage may be reviewed and/or permitted as part of the MSS. However, these modifications will need to follow the appropriate levels of approvals. Any modification to the hydrological regime of either Mud Creek (Thomas Baxter Municipal Drain) or Rideau River (Hawkins Municipal Drain) will need to be completed in accordance with the Drainage Act. Minor adjustments to the drainage divide between sub-watersheds are generally permitted while a significant diversion may trigger the requirement of additional investigations. This requirement would permit the

evaluation of the impact on the natural environment and the identification of mitigation measures. Should there be an adjustment contemplated with the drainage divide, the MSS would then be the vehicle that would determine whether the proposed mitigation measures are adequate or, alternatively, if there will be a need to complete a Schedule C Class EA.

B8.1.1 Area Tributary to the Jock River

Historically, three (3) municipal drains provided conveyance to the Jock River. However, these drains are being enclosed and abandoned as the urban development extends south. The former Todd Municipal Drain is now enclosed downstream of the Todd Pond, the Clarke East Municipal Drain is now partially enclosed, and there are plans for the Clarke West Municipal Drain to be partially enclosed as development proceeds. Where partial enclosure is proposed, the works will be subject to the requirements of the Federal Fisheries Act. Modification or abandonment of these municipal drains will need to be completed in accordance with Section 78 of the Drainage Act, chapter D.17, R.S.O. 1990. Based on topography, approximately 99 ha of the study area (refer to the drainage limits depicted in **Figure 5-1**) is tributary to the Jock River.

B8.1.2 Area Tributary to Mud Creek

The Thomas Baxter Municipal Drain is immediately south of the Study Area at Barnsdale Road and carries flow from Barnsdale Road to Mud Creek. There are no plans to abandon or enclose the drain. Based on topography, approximately 11 ha of the southwestern portion of the study area (refer to drainage limits depicted on **Figure 5-1**) is tributary to Mud Creek via the above-noted Drain. In July 2016 the Council approved the appointment of Robinson Consultants Ltd to prepare a report under Section 78 of the Drainage Act to inform the Council of any drainage works projects required on the Municipal Drain as a result of the future servicing of the BSUEA.

B8.1.3 Area Tributary to the Rideau River

The area tributary to the Rideau River drains via roadside ditches along Barnsdale Road and the existing Greenbank Road which in turn drains to the Hawkins Municipal Drain system to the east of the existing Greenbank Road and south of Barnsdale Road. Based on topography, approximately 13 ha of the southeastern portion of the study area (refer to the drainage limits depicted in **Figure 5-1**) is tributary to the Rideau River via the above-noted Drain. In July 2016 the Council approved the appointment of Robinson Consultants Ltd to prepare a report under Section 78 of the Drainage Act to inform the Council of any drainage works projects required on the Municipal Drain as a result of the future servicing of the BSUEA.

B8.2 Aquatic Habitat and Natural Heritage

Natural heritage features have been identified by Dillon Consulting in their March 2016 report based on the fieldwork undertaken. The report was prepared to identify, amongst other features, wetlands and fish habitat. Based on this undertaking, there were no watercourses found within the study area, and the only water features identified were man-made ponds resulting from aggregate extraction.

B8.3 Floodplains

Lands which are part of the BSUEA are not restricted by any regulation floodplains.

B8.4 Water Quantity Control

Water quantity criteria will be affected by site constraints and municipal and provincial requirements. Water quantity control for lands that drain to the Jock River will be governed by available capacity in existing and planned minor and major systems in the existing Barrhaven South Community. Since the existing and planned infrastructure was designed to service lands up to the current Urban Boundary, there is limited or no available capacity in existing and planned minor and major systems. Table 8-1 summarizes the minimum residual capacity of trunk sewers, the minimum freeboard between USF, and the 1:100 year HGL and maximum street ponding depth for each stormwater management facility (SWMF) outlet. As shown in **Table 8-1** below, all minor systems are either close to or exceeding the minimum allowable freeboard between HGL and USF of 0.30 m as required by the Design Guidelines. Additionally, the major system through which the Todd Pond outlets does not meet the maximum allowable street ponding depth (static and dynamic) of 35 cm per Technical Bulletin PIEDTB-2016-01.

For lands that drain to Mud Creek, flows will need to be limited to the capacity of the Thomas Baxter Drain. Any additional flow discharge to the Thomas Baxter Drain should not aggravate the risk of flooding. Any modifications to this Drain or to its flow regime will need to be assessed and approved in accordance with Section 78 of the Drainage Act, Chapter D.17, R.S.O., 1990.

In addition, Barnsdale Road is classified as an arterial roadway, which means that major flow from events up to the 1:100 year may not be conveyed across it.

Similarly, lands tributary to the Rideau River will be subject to the capacity limits of the downstream watercourse, namely, the Hawkins Municipal Drain as well as the overland flow conveyance restrictions due to the arterial road. Any additional flow discharge to the Hawkins Municipal Drain should not aggravate the risk of flooding. Any modifications to this Drain will need to be assessed and approved in accordance with Section 78 of the Drainage Act, Chapter D.17, R.S.O., 1990.

Table 8-1: Available Capacity in Existing and Planned Minor and Major Storm Systems in Barrhaven South

Outlet (SWMF)	Sewer Status	Minimum available capacity in trunk storm sewers	Minimum clearance (freeboard) between 1:100 yr & USF	Maximum street ponding (static + dynamic)
Corrigan Pond	Existing	735 L/s (MH 105-106A) (1)	0.32 m @ MH 104B on the existing Greenbank Road (2)	0.35m (3)
Todd Pond	Existing	136 L/s (MH 643-640) (5)	0 m (i.e., no freeboard, HGL is 0.23 m above USF and 0.02 m below basement floor) (5)	11 roadway sags with flow depth in excess 400 mm (5)
Clarke Pond	Planned	237 L/s (MH 211-211A) (6)	Not available - conceptual HGL at 0.08 m below T/G of MH 304 (4)	Information has not been reported
Cedarview Pond	Planned	165 L/s (MH 506-505) (6)	Not available, conceptual HGL at 0.20 m below T/G of MH 304 (6)	Information has not been reported
Greenbank Pond	Planned	167 L/s (MH415-409) (6)	Not available, conceptual HGL at 0.47m below T/G of MH N403A (6)	Information has not been reported

Within the BSUEA, the realigned Greenbank Road will be classified as an arterial road; major overland flow generated by events up to 1:100 year will, therefore, not be able to cross the realigned Greenbank Road. Since the realigned Greenbank Road will bisect the BSUEA, this restriction on overland flow conveyance will have implications for stormwater management within the development.

B8.5 Water Quality Control

Water quality treatment will need to be provided in accordance with the relevant subwatershed studies. The Jock River Reach One Subwatershed Study states that, for areas tributary to the Jock River, an enhanced level of water quality treatment, in accordance with the MOE 2003 SWMPDM, is required. It is noted that currently all existing and planned SWMFs in Barrhaven South exceed the MOECC water quality storage requirement to achieve an enhanced level of protection for their current drainage areas, as summarized in **Table 8-2,** below.

Table 8-2: Water Quality Storage Assessment for Existing and Planned SWMFs

SWMF	SWMF Status	Water Quality Storage (m^3) in Excess of Minimum MOECC Requirements	
		Wet Permanent Pool	Extended Detention Volume
Corrigan Pond	Existing	1700 (1)	100 (1)
Todd Pond	Existing	6936 (2)	Information has not been reported
Clarke Pond	Planned	2804 (3)	Information has not been reported
Cedarview Pond	Planned	211 (4)	Information has not been reported
Greenbank Pond	Planned	582 (4)	Information has not been reported

Notes

(1) As per IBI June 9, 2015 Letter Report - Corrigan SWM Facility

(2) As per JFSA April 2015 Todd Pond Model Keeper Re-Assessment of Existing System Capacity (Appendix E)

(3) As per JFSA July 25, 2013 Todd Pond and Clarke Pond Model Keeper Analysis / Update of Half Moon Bay South Subdivision Plan

(4) As per Stantec Draft 2014 BSMSSA

The Mud Creek Subwatershed Study does not make any specific water quality protection requirements but states that surface water contamination from point and non-point sources must be managed. Additionally, the Lower Rideau Subwatershed Study has set an objective to manage the quality and quantity of non-point source runoff and to manage surface and groundwater contamination from point source discharges.

B8.6 Infiltration

The Hydrogeological Study undertaken by Paterson confirms that, in general, soils within the BSUEA have a moderate to high hydraulic conductivity (refer to Figure C-1 and Figure C-2, **Appendix 'B3'**). The moderate are observed in the eastern portion while the highest are observed in the northwestern portion of the study area. Such soils are considered to act as a recharge zone for underlying aquifers. The presence of soils with high hydraulic conductivity means that the site is suitable for providing groundwater recharge and appropriate practices must be implemented to maximize the rate of infiltration.

Non-structural Best Management Practices such as discharging impervious runoff, including roof runoff, to lawns are required regardless of soil capacity, in accordance with the Jock River Reach One Subwatershed Study. In addition, the study should consider the potential to incorporate LID in areas that are conducive to infiltration, to reduce the anticipated infiltration deficit and maintain pre-development infiltration levels.

Based on fulfilling the objective of maintaining pre-development infiltration levels, storm servicing solutions incorporating infiltration measures will be developed at the MSS in order to achieve a water balance. These infiltration measures will be incorporated within all areas of the BSUEA, striving to maintain pre-development infiltration levels for the Jock River, Rideau River (via the Hawkins Municipal Drain), and Mud Creek (via the Thomas Baxter Municipal Drain) sub-watersheds. As part of storm servicing, some constraints such as modification to drainage may be reviewed and/or permitted as part of the MSS. However, these modifications will need to follow the appropriate levels of approvals. Any modification to the hydrological regime of either Mud Creek (Thomas Baxter Municipal Drain) or Rideau River (Hawkins Municipal Drain) will need to be completed in accordance with the Drainage Act.

Any future redevelopment of the sand and gravel resource area, as per Official Plan policy 3.7.4, should ensure that the groundwater recharge function be maintained.

The Mud Creek Subwatershed Study identified that there are significant groundwater recharge areas including the Kars Esker, a Mississippi-Rideau Sourcewater Protection Region Significant Groundwater Recharge Area, across the majority of the western portion of the BSUEA. These pre-development recharge conditions must be maintained. A water balance will be required to demonstrate adherence to this requirement. The Mud Creek Subwatershed Study also recommends avoiding infiltration of poor quality runoff from paved surfaces without pre-treatment, and to consider the use of LID and Best Management Practices for stormwater management quality and quantity control.

B8.7 Existing Servicing Infrastructure

The following opportunities and constraints have been identified for the existing and planned servicing infrastructure in Barrhaven South. These will be reviewed and evaluated in greater detail as part of the BSUEA MSS.

B8.7.1 Wastewater Servicing

Wastewater servicing for the BSUEA is ultimately governed by the available residual capacities in the existing downstream trunk sanitary sewers in Barrhaven South. Based on the theoretical available residual capacities for existing trunk sanitary sewers identified in Section B7.1 of this Report, an approximate equivalent residential development area was calculated using an average peak flow rate per hectare of 1.77 L/s/ha. This average peak flow rate is based on an average unit density of 34 units/ha (as per the 2006 Barrhaven South CDP) a population density of 2.7 persons/unit, an average flow rate of 350 L/cap/day, a residential peaking factor of 4.0, and an infiltration allowance of 0.28 L/s/ha in accordance with the Design Guidelines. It is noted that a peaking factor of 4.0 is relatively high; however, it provides a more

conservative estimate. Based on an average peak flow rate of 1.77 L/s/ha, it appears that the existing trunk sanitary sewers could service the following future residential development:

Table 8-3: Available Tributary Area Capacity in Existing Trunk Sanitary Sewers

Trunk Sanitary Sewer	Residual Capacity (L/s)	Equivalent Residential Development Area (ha)
Existing Greenbank Road	295.4	167
Cambrian Road	51.4	29
River Mist Road	14.4	8

As indicated in Section **B7.1** of this Report, the existing Greenbank Road trunk sanitary sewer serves as the main outlet for the existing Barrhaven South sanitary sewer system, which includes the Cambrian Road and River Mist Road trunk sanitary sewers. Based on the theoretical peak flow calculations summarized in **Table 8-3** above, the existing Greenbank Road trunk sanitary sewer has sufficient capacity to accommodate the peak flows generated within the BSUEA. It can accommodate approximately 167 ha of additional residential area, which is more than the 121 ha area of the BSUEA. Furthermore, based on the conclusions of the 2013 IMP wastewater model, total peak flows conveyed downstream of the existing Greenbank Road trunk sanitary sewer at MH 522A (located at the intersection of Half Moon Bay Road, immediately south of the Jock River) should be limited to 590 L/s to prevent potential adverse impacts to the HGL in the existing downstream sanitary sewer system. Stantec concluded in the 2013 Wastewater Collection System Assessment that downstream wastewater infrastructure, including the SNC and WRC, could accommodate a peak flow of 590 L/s from the Barrhaven South Community and the BSUEA, with no risk of surcharging and/or basement flooding.

It should also be noted that based on the depth of the existing Greenbank Road trunk sanitary sewer at the current Urban Boundary (i.e., obvert elevation of 91.77 m) and the groundwater elevations observed by Paterson within the eastern portion of the BSUEA (i.e., ± 95.00 m), it is anticipated that a portion of the trunk sanitary sewer near the eastern limit of the BSUEA will be lower than the groundwater table. This could result in increased infiltration into the sewer system and lowering of the groundwater table.

B8.7.2 Water Servicing

Low pressures (i.e., less than 40 psi) are anticipated during domestic water demand conditions in the BSUEA in localized areas where the existing ground elevation is relatively high. Further opportunities and constraints will be identified upon completion of a detailed Hydraulic Network Analysis (HNA) as part of the BSUEA MSS.

B8.7.3 Stormwater Servicing and Stormwater Management

Stormwater servicing and SWM opportunities and constraints associated with each existing and planned SWMF outlet in the Barrhaven South Community are summarized in Table 8-4.

Table 8-4: Stormwater Servicing and SWM Opportunities and Constraints in Barrhaven South

SWMF Outlet	Opportunity	Constraint
Corrigan Pond	Available residual capacity in existing sewers and pond storage volume	Max Ponding depth of 35 cm & min HGL freeboard of 32 cm
Todd Pond	Available residual capacity in existing sewers pond storage volume	Max. ponding depth & min. HGL freeboard not being met
Clarke Pond	Available residual capacity in planned sewers and pond storage volume	Minimal HGL freeboard anticipated
Cedarview Pond	Available residual capacity in planned sewers and pond storage volume	Minimal HGL freeboard anticipated
Greenbank Pond	Available residual capacity in planned sewers and pond storage volume	Minimal HGL freeboard anticipated
Notes Refer to **Table 8-1** and **Table 8-2 above** for details		

Although all five (5) existing/planned SWMFs in Barrhaven South have residual water quality volumes, as shown in **Table 8-2**, and have available residual capacity in their associated trunk infrastructure, as shown in **Table 8-1**, all storm sewer systems in Barrhaven South are ultimately limited by high HGL elevations. The Corrigan and Todd Ponds are also limited by the major system ponding depths which are generally at or exceeding the maximum allowable depth of 0.35 m. Although the planned trunk storm sewers are anticipated to have high HGL elevations as per the Draft 2014 BSMSSA, opportunities to provide stormwater servicing and SWM for the BSUEA via the three (3) planned wet pond facilities (Clarke, Cedarview and Greenbank) and their associated trunk storm sewers will be reviewed in detail and evaluated as part of the BSUEA Master Servicing Study (MSS).

In addition, as noted in Section **B7.3.2** of this Report, both minor and major system flows generated from the 5.6 ha parcel of land owned by Mattamy within the BSUEA (i.e., east of the future realigned Greenbank Road) were allocated to the Todd Pond under an 'ultimate' scenario as part of the 2015 Clarke Pond Model Keeper Analysis completed by JFSA. Their analysis showed that the Todd Pond can provide adequate water quality control for this future development land if the length of the facility outlet weir is extended from 30 m to 48 m. Servicing this 5.6 ha land parcel via the Todd Pond would, however,

require that the City accept a deviation from their Guidelines with respect to minimum freeboard to the underside of footing, as well as to the maximum street ponding depth.

B9.0 SUMMARY AND RECOMMENDATIONS

The following provides a series of recommendations to be considered when preparing the BSUEA MSS, in the context of the opportunities and constraints discussed above.

B9.1 Wastewater Servicing

Assuming that the Brazeau and Drummond lands (totalling ± 45 ha) will ultimately be developed as commercial/employment, it is anticipated that the northern portion of the BSUEA will be serviced by the planned trunk sanitary sewers along the Future Collector Road and/or the future realigned Greenbank Road, which both converge at the Cambrian Road trunk sanitary sewer (refer to **Figure 7-1**). It should be noted that **Figure 7-1** indicates obvert elevations at the upstream end of the Future Collector and future realigned Greenbank Road trunk sanitary sewers, in accordance with the Draft 2014 BSMSSA; however, opportunities to reduce the slope and lower the upstream obvert elevation of these future sewers will be reviewed as part of the MSS. Revisions to the design of these future sewers at the MSS stage are anticipated, to improve the serviceability of the existing low-lying aggregate pit areas within the northern portion of the BSUEA.

It is anticipated that the 5.6 ha parcel of land owned by Mattamy east of the future realigned Greenbank Road within the BSUEA will be serviced by the existing River Mist Road trunk sanitary sewer as per the existing Half Moon Bay Phase 3 design. It is also anticipated that the Mattamy lands west of the future realigned Greenbank Road will outlet to the River Mist Road trunk sanitary sewers either via the Half Moon Bay or Quinn's Pointe local sanitary sewers. Based on the natural topography of the remaining 66 ha of the BSUEA, it is anticipated that these lands could outlet by gravity to the existing Greenbank Road trunk sanitary sewer.

To minimize infiltration into the existing Greenbank Road sanitary sewer system where it is anticipated to be below the groundwater table (i.e., eastern portion of the BSUEA), the following measures can be assessed and implemented:

- Concrete pressure pipe (CPP);
- Higher class PVC pipes;
- Higher percentage silica fume in maintenance hole structures;
- Cretex seals in maintenance holes; and

- Clay seals along the service trench.

B9.2 Water Servicing

Water servicing for the BSUEA will be developed to fulfill regulatory requirements under both domestic and fire flow conditions. It is anticipated that there will be an area in the BSUEA that will not fulfill the minimum pressure requirements during domestic demand conditions, due to topography. As a result, this localized area may require a booster pumping station or, alternatively, oversized services combined with jet pumps. This condition, as well as water servicing specifics such as watermain looping and sizing of the feedermains for the BSUEA, will be addressed at the MSS stage by a hydraulic network analysis (HNA). The HNA for the BSUEA MSS will be carried out in accordance with the most recent Design Guidelines and Technical Bulletins.

B9.3 Stormwater Servicing and Stormwater Management

The planned trunk storm sewer along the Future Collector Road, which outlets to the future Clarke Pond, is anticipated to have the lowest upstream obvert elevation (at the northern limit of the BSUEA) compared to the other planned and existing trunk storm sewers surrounding the Study Area, as indicated in **Figure 7-3**. For this reason, the Future Collector Road trunk storm sewer would be the optimal minor system outlet for the existing low-lying aggregate pit areas within the northern portion of the BSUEA. This servicing strategy would, however, have to be reviewed in conjunction with JFSA (the Clarke Pond model keeper) to assess whether the planned Future Collector trunk storm sewer and the Clarke Pond could be designed to accommodate these additional lands.

Opportunities to utilize the future Cedarview Pond as a minor system outlet for the BSUEA will also be reviewed and assessed as part of the MSS. It should be noted that since both the future Clarke and Cedarview Ponds are planned to be located north of Cambrian Road, which is an arterial roadway, major system flows up to the 1:100 year would have to be contained upstream of Cambrian Road using a dry pond facility.

Should a new wet pond facility be required to provide SWM for the southern portion of the BSUEA, then the naturally low-lying topography at the southeastern corner of the Study Area would be the optimal location. It is anticipated that this pond could provide both stormwater quantity and quality control and could potentially outlet to the existing Greenbank Road trunk storm sewer. Quantity control would be required so that the integrity of the existing Greenbank Road storm sewer system is maintained. Major system flows could also be conveyed overland to this future wet pond, with the exception of those generated west of the future realigned Greenbank Road. Since this road is designated as an arterial roadway, major system flow up to the 1:100 year event generated within the BSUEA lands west of the future realigned Greenbank Road would

either have to be contained within a separate dry pond facility or captured via an oversized minor system and conveyed beneath the future realigned Greenbank Road.

Depending on the preferred SWM selected to service the BSUEA, it is anticipated that diverting some stormwater away from the Thomas Baxter Municipal Drain (Mud Creek) towards the Jock River may occur. The impact of diverting a small proportion of the watershed should have minor significance to the watercourse since the continuous simulation modeling found that there is no surface runoff response in events smaller than a 1:5 year event. The MSS will outline any requirements, triggered by a change in watershed boundaries, to meet the Municipal Class Environmental Assessment process, including if a Schedule C EA is required as a result of the selected SWM strategy.

LID measures to promote infiltration are to be incorporated as part of the overall servicing of the BSUEA to achieve the targeted water balance for each of the three (3) subwatersheds. Special attention should be devoted towards infiltrating "clean water" across the area of the Kars Esker while Best Management Practices (BMPs) to reduce runoff should be included in all locations where there is an increase in imperviousness. BMPs can include draining roofs to rear-yards and increasing vegetation areas.

SYNOPSIS OF BACKGROUND DOCUMENTS

EXISTING CONDITION REPORT – APPENDIX B1
SYNOPSYS OF BACKGROUND DOCUMENTS

MINTO COMMUNITIES INC. & MATTAMY HOMES LTD.
BARRHAVEN SOUTH URBAN EXPANSION AREA

1.0 REPORTS COVERING A LARGE GEOGRAPHICAL AREA WHICH ENCOMPASS THE SITE

1.1 *Jock River Reach One Subwatershed Study Final Report*. Stantec Consulting Ltd. (June 2007). City of Ottawa

In 2005 the Jock River Reach One Subwatershed Study (JRROSS) was undertaken by Stantec on behalf of the principal landowners and the City of Ottawa in response to the growing development pressures in Barrhaven and surrounds. The subwatershed study was completed to identify the existing environmental condition of the river and associated natural resources and to provide the environmental and conceptual stormwater management requirements to allow for the Barrhaven South Community and other areas within the subwatershed to be developed while protecting, restoring or enhancing the significant natural features and functions. .The subwatershed study was meant to support a Community Design Plan that was being undertaken in parallel to the study for the lands located south of the Jock River.

The study found that all tributaries of the Jock River, including the main tributaries south of the Jock River (West Clarke Drain, East Clarke Drain and Todd Drain), support fisheries however they provide only highly seasonal and marginal fish habitat for a handful of warm water tolerant fish species. The tributaries can run dry or low after high spring water levels and they have been largely modified by channel straightening. Other features of the subwatershed identified in the report south of the Jock River included:

- Five woodlots considered significant woodlands, two of which contain forest interior habitat;
- Recharge area function is associated with the sand and gravel resource areas south of Cambrian Road; and,
- The Jock River is classified as a Policy 2 watercourse for phosphorus which requires a net reduction in phosphorus loadings to the river.

The resulting Stormwater Management Design Criteria for the areas south of the Jock River includes:

- Quantity control storage as required by the capacity of rehabilitated tributaries

- No erosion control storage required as the rehabilitated tributaries should be designed to withstand the erosive forces of stormwater runoff;
- Quantity control as per the Ministry of the Environment's enhanced level treatment (80% Total Suspended Solids (TSS) removal);
- All stormwater management facility outlets to be designed to augment low flows to the extent possible; and,
- Structural infiltration practices to be implemented in areas of suitable soil and non-structural best management practices should be implemented elsewhere to reduce the magnitude of system runoff.

The South of Jock River Management Plan which results from the design criteria includes the following recommendations:

- One centralized stormwater management facility (wet pond) for each of the Cedarview catchment area and West Clarke Drain catchment area. Two centralized facilities in the Todd Drain catchment area;
- The partial closure of West Clarke Drain, the full enclosure of East Clarke Drain and the rehabilitation of the remaining drains to convey stormwater to the Jock River. The partial closure of Todd Drain and the rehabilitation of the remaining Todd Drain to convey flows to the Jock River;
- Protection of the significant woodlands identified in Cedarview catchment area and conservation and integration, where feasible, of the woodlot in the West Clarke Drain catchment area; and,
- Creation of new fish habitat areas for loss of the closed drains in accordance with the Barrhaven South Conceptual Fish Habitat Compensation Plan.

1.2 *Jock River Subwatershed Report 2010: A report on the environmental condition of the Jock River*. Rideau Valley Conservation Authority. (April 2011).

The latest subwatershed report card for the Jock River was released by the Rideau Valley Conservation Authority in 2010 and is due for review in 2016. The report looks at the subwatershed in terms of four indicators: forest cover, wetlands, riparian cover and water quality. The Jock River subwatershed is broken up into 12 catchment areas with part of the study area covered by the data sheet for the Barrhaven Catchment. The data sheet provides data on the catchment features and summarizes the catchment under the four areas of surface water quality, riparian zone conditions, catchment land cover, groundwater resources, surface water resources and watershed monitoring projects.

For the Barrhaven catchment of the Jock River:

- the water quality is Fair with 11 exceedances of E.coli and 65 exceedances of Total Phosphorus against provincial guidelines in the period 2004 to 2009;
- the riparian margin (30 metres adjacent land cover) is 56% vegetated compared to a recommended 75%;
- 63% of instream habitat has had some significant human alterations;
- the 335 ha of woodlands occupies 11% of the drainage area which is below the minimum 30% recommended in order to sustain forest bird species;
- the shallowest underlying bedrock aquifers are considered to be vulnerable to land use impacts due to the thin overlying protective soil cover though this is not considered an existing problem; and,
- there are rural clean water projects and tree planting projects within the area and 15% of the drainage area is within regulation limits which affords protection to the habitat and water resource systems.

1.3 *Mud Creek Subwatershed Study*. City of Ottawa, Planning and Growth Management. (October 2015).

1.4 *Mud Creek Subwatershed Existing Conditions Report Phase I Summary*. City of Ottawa Land Use and Natural Systems Policy Group. 2011.

1.5 *Jock River Reach 2 & Mud Creek Subwatershed Study Existing Conditions Report (Final)*. Marshall Macklin Monaghan Limited and Water & Earth Sciences Associates. (May 2009). City of Ottawa.

The Mud Creek Subwatershed drains to the Rideau River just north of the Village of Manotick. The subwatershed also includes Mahogany Creek, a small catchment adjacent to Mud Creek, which drains directly to the Rideau River. In 2003 a joint subwatershed study was initiated with Mud Creek and Reach 2 of the Jock River however delays to the process meant that the full process was never realised after the Existing Conditions Report was published in 2009. A summary report was published by the City in 2011 with intent to start Phase II. The project was fully restarted in 2015 as a new subwatershed study undertaken by the City of Ottawa, with information collated from studies by the City of Ottawa and the Rideau Valley Conservation Authority, to examine the existing conditions of the subwatershed and identify any actions which would be required to improve the environmental health and condition of the subwatershed over the long term.

The issues and opportunities identified in the study included the following which may be relevant within the Barrhaven South Urban Expansion Area:

- Mud Creek is a cool-water system with a variety of fish species, however water quality is being negatively impacted by runoff from adjacent land uses;

- The Kars Esker is a valuable source of groundwater and is recognized in the Source Water Protection Plan as a highly vulnerable aquifer; and,
- The subwatershed includes several features contained in the City's natural heritage system including significant woodlands and unevaluated wetlands.

The report has made several recommendations some of which may have impacts within the Study Area:

- Existing programs offered by the City of Ottawa and the Rideau Valley Conservation Authority should be used to encourage stewardship of the creeks and other aquatic features;
- The significant groundwater recharge area (including the feature known as the Kars Esker) should be appropriately protected under the development review process;
- Sections of Mud Creek which have been identified as significant valley-lands or linkages should be added to the Natural Heritage System overlay in the City's Official Plan and although the unevaluated wetlands should not be added they should be considered as subject to the Official Plan policies for the protection of the Natural Heritage System.

1.6 *Lower Rideau River Subwatershed Report 2012: A report on the environmental condition of the Lower Rideau River.* Rideau Valley Conservation Authority. (February 2013).

The latest Subwatershed Report Card for the Lower Rideau River was issued by the Rideau Valley Conservation Authority in 2012. The Lower Rideau River watershed is broken up into 16 catchments, one of which is the Mud Creek subwatershed. The individual catchment reports contains information on the general subwatershed, water quality, riparian vegetation and aquatic habitat, land use, and stewardship and protection. For the Mud Creek catchment:

- The water quality rating dropped to Poor for the 2006-2011 period partly due to an increase in E-Coli contamination, continued contamination from heavy metals and low readings of benthic invertebrates;
- The riparian margins are 45% and 54% vegetated on the left and right banks respectively, compared to a recommended target of 75%;
- Approximately 26% of the instream habitat has had some human alteration;
- Only 19% of the catchment area is woodlot, below the minimum 30% recommended for preservation of forest bird species; and,
- there are rural clean water projects and tree planting projects within the area, however only 1% of the drainage area is within regulation limits which means limited protection to the habitat and water resource systems.

1.7 *Lower Rideau Watershed Strategy Final Report*. Aquafor Beech / Robinson Consultants Inc. (September 2005). Rideau Valley Conservation Authority

The Lower Rideau Subwatershed Strategy was prepared in 2005 by Aquafor Beech Ltd and Robinson Consultants for the Rideau Valley Conservation Authority. The strategy initiative began in 2002 in order to adopt an ecosystem based approach to the responsibilities for the watershed and river management within the Lower Rideau watershed which includes the Mud Creek subwatershed. The strategy was developed through consensus at the Technical Advisory Committee level with the conservation authority, City of Ottawa and provincial and federal organisations part of the committee. The major issues identified as needing to be addressed included:

- Loss of headwater tributaries due to rural and urban drainage practices and channelization of those tributaries that remained;
- Removal of natural riparian vegetation which coupled with altered hydrology results in instream erosion and loss of habitats leading to reduced biodiversity and poor quality fish communities; and,
- Excessive nutrient loading from land use activities both agricultural and urban which often resulted in levels exceeding provincial guidelines.

An Adaptive Management Strategy was created with a series of actions to address the key issues. The implementation of the strategy is being managed through a three tier working group structure composing of the Lower Rideau Watershed Management Steering Committee, The Lower Rideau Watershed Strategy Implementation Committee and the Lower Rideau Watershed Management Working Groups with a working group for each of the following priority management actions:

- Public Education and Community Outreach to promote a conservation ethic to landowners and develop a streamlined approval process;
- Managing inputs of nutrients, bacteria and other contaminants to develop new stormwater management standards and improve current stormwater runoff quality;
- River and stream corridor management to prioritize the completion of subwatershed studies, protect, manage and rehabilitate the riparian margin, and protect habitats;
- Control of flows and water levels to improve the management of spring/fall water levels and address fisheries concerns; and,
- Integrated watershed monitoring and reporting to integrate monitoring programs and ensure that the correct parameters and indicators are being collected.

1.8 *Barrhaven South Official Plan Amendment Submission*. David McManus Engineering Ltd. (August 2008). Minto Communities Inc.

In August 2008 Minto Communities, on behalf of themselves and adjoining landowners, submitted a report in support of amending the City of Ottawa's Official Plan to include an urban expansion of the Barrhaven South Community Design Plan. The amendment submission covered a wider area than the current study area, east from Borrisokane Road to Prince of Wales Drive north of Barnsdale Road to the urban boundary.

The report presented a land use plan for the site with a focus on residential development with some employment or industrial areas. Servicing requirements for the Barrhaven South amendment area were presented along with recommendations for enabling the servicing requirements to be met. The recommendations included:

- Water infrastructure could be serviced from the adjoining Zone BAR with a 15% increase in demand met with improvements already required in the adjoining zone and relocation of a proposed water tower for Manotick Village closer to the service area;
- Sanitary loading could result in a 10% increase in flows in the West Rideau Collector and overall system infrastructure studies may be required to determine surcharges to be expected at full build-out;
- Stormwater servicing would utilise existing infrastructure and construct post to pre management facilities to control flows; and,
- Transportation network improvements would be required but these could be covered through development charges.

The report set out a rationale that the proposed boundary expansion to the amendment lands would be consistent with the Provincial Policy Statement and policies of the City of Ottawa's Official Plan.

1.9 *Aggregate Resource Designated Lands Study, 3882 Barnsdale Road, Ottawa, Ontario*. Paterson Group Inc. (February 2012). Minto Communities Inc.

An assessment of the viability of lands as an extractable resource was carried out in consideration of the lands immediately north of Barnsdale Road between Borrisokane Road and Greenbank Road. The work included investigation by means of compiling all available site specific borehole and test pit data of the subsurface conditions, determination of the suitability of the aggregates based on gradations and provision of an assessment of viability of the site for future extraction. A total of 27 test pits were analysed and the findings indicated that the site does not contain aggregate suitable for

extraction but there is suitable geotechnical conditions to support residential development with gravity servicing and conventional foundations.

2.0 SITE SERVICING STRATEGIES FOR ADJACENT URBAN DEVELOPMENT SITES

2.1 Barrhaven South Master Servicing Study Final Report. Stantec Consulting Ltd. (June 2007). City of Ottawa.

In 2007, Stantec completed the BSMSS to identify wastewater, stormwater and potable water servicing strategies for Barrhaven South up to the current Urban Boundary. These strategies are as follows:

- A network of trunk sanitary sewers to convey wastewater generated from the BSC to a main trunk sanitary sewer on Greenbank Road and ultimately to the South Nepean Collector (SNC) and the West Rideau Collector (WRC);
- Stormwater servicing and stormwater management based on the preferred SWM approach identified in the 2007 Jock River Reach One Subwatershed Study consisting of five wet pond facilities to provide quality control (80% TSS removal) before discharging to the Jock River; and
- A network of collector watermains to provide potable water to the BSC fed by existing transmission watermains on Woodroffe Avenue and Fallowfield Road which are boosted by the existing Barrhaven Pump Station and the existing Barrhaven Reservoir.

2.2 *2013 Infrastructure Master Plan Wastewater Collection System Assessment.* Stantec Consulting Ltd. (September 17, 2013). City of Ottawa.

This City-wide wastewater collection system assessment was completed by Stantec to identify system upgrades required to accommodate projected growth up to 2031 and 2060. Findings presented in this report served as the basis for the wastewater component of the City's 2013 Infrastructure Master Plan.

2.3 *City of Ottawa 2013 Water Master Plan.* Stantec Consulting Ltd. (September 20, 2013). City of Ottawa.

This City-wide water supply and distribution system assessment was completed by Stantec to determine upgrade requirements to meet growth, reliability and renewal needs within the 2031 and 2060 planning horizons. Findings presented in this report served as the basis for the water component of the City's 2013 Infrastructure Master Plan.

2.4 *Infrastructure Master Plan. City of Ottawa. (November 2013).*

The purpose of the City of Ottawa's IMP is to support the City-wide Official Plan by ensuring that there is sufficient infrastructure capacity to support the development and redevelopment levels contained within the Official Plan. The IMP sets out to achieve this by taking high level directions on infrastructure growth, operation and renewal for the planning horizon of the Official Plan, until 2031 and beyond until 2060.

2.5 *Barrhaven South Master Servicing Study Addendum Draft Report.* Stantec Consulting Ltd. (November 2014). City of Ottawa.

In 2014, Stantec issued a draft Addendum to their original 2007 BSMSS document. This Addendum incorporated new design parameters prescribed in the updated 2012 Ottawa Sewer Design Guidelines (herein referred to as the Design Guidelines) as well as the detailed design of three Barrhaven South residential developments that were completed since the issuance of the original 2007 BSMSS. These developments include Mattamy's Half Moon Bay, Tamarack's The Meadows at Half Moon Bay and Mattamy's Half Moon Bay South. Specific revisions to the servicing strategies included:

- Updates to sanitary peak flows based on actual unit counts in the three aforementioned residential developments;
- Updates to the stormwater servicing and SWM analysis based on design criteria established in the 2012 Design Guidelines and subsequent Technical Bulletins as well as updates to storm drainage areas based on the detailed designs for Half Moon Bay, The Meadows and Half Moon Bay South; and
- An updated hydraulic model for the water distribution network based on the 2010 City of Ottawa Water Distribution Guidelines and the 2013 Ottawa Water Master Plan Update (WMPU).

2.6 *Manotick Master Drainage Plan Phase I.* A.J. Robinson and Associates Inc. (October 1993). Township of Rideau.

2.7 *Manotick Master Drainage Plan Phase II.* Robinson Consultants Inc. (February 1996). Township of Rideau.

Work on preparation of a Master Drainage Plan for Manotick was started in 1990. Phase I was completed in 1993 and Phase II commenced following work on a Secondary Plan for Manotick and was completed in 1996. The Master Drainage Plan covers the area of Manotick and the Mud Creek catchment south of Baxter Road and east of First Line Road. The plan study area includes the point at which the Thomas Baxter Municipal Drain from the south of the BSUEA flows into Mud Creek.

The report made recommendations which mostly related to drainage in Manotick but some of which may affect the BSUEA discharges in the Mud Creek catchment. The report found that erosion control is required along some sections of Mud Creek which the report proposed could be addressed through stabilization and vegetation planting and also potentially check dams to control velocities. Two online wet ponds were included in the Master Drainage Plan, one at the downstream end of Mud Creek and one at the confluence with the Wilson-Cowan Drain. In addition, the report recommended that measures should be considered to reduce peak flows from future developments within the Manotick Drainage Master Plan area, however no specific control targets were included in the report. There were no targets set for quality control in the recommendations.

3.0 SURROUNDING INFRASTRUCTURE REPORTS

3.1 *Corrigan Stormwater Management Facility Stormwater Management Report and Design Brief*. IBI Group (July 2010). McNeil Farm Limited

The Corrigan SWMF SWM Report and Design Brief was first issued by IBI in 2008 and later updated in July 2010 to incorporate the detailed designs of development completed in Barrhaven South since 2008. The Corrigan Pond is an end-of-pipe SWMF located south of the Jock River and east of Greenbank Road and is part of the servicing strategy outlined for Barrhaven South in the 2007 Jock River Reach One Subwatershed Study and the 2007 BSMSS. The facility was designed to service a 145 ha tributary area and provide 80 % TSS removal before outletting to the Jock River.

3.2 *Stormwater Management Barrhaven South.* IBI Group (October 2014). Minto Communities Inc.

In October 2014, IBI issued a report entitled “Stormwater Management Barrhaven South” to support the development of Minto’s Quinn’s Pointe subdivision (formerly referred to as Barrhaven South Phase 1) as well as to provide an updated SWM analysis for the Corrigan Pond based on parameters prescribed in the 2012 Design Guidelines and subsequent Technical Bulletins. Although major system flows from Quinn’s Pointe were originally allocated to the Todd Pond, IBI indicated that the proposed Quinn’s Pointe development would exceed the allowable major system release rate allocated as part of the Todd Pond design. Therefore, IBI proposed a dry pond at the south end of Minto’s lands to capture major overland flows before releasing, at a restricted rate, back into the minor system.

3.3 Respond to the City of Ottawa Comment – Corrigan SWM Facility. IBI Group (June 9, 2015). J.L. Richards and Associates Limited.

In June 2015, IBI Group issued a letter in which they confirmed that the existing Corrigan Pond exceeds the water quality volume requirement to achieve 80% TSS removal for its current tributary area of 147.5 ha. This represented an increase in tributary area of 2.5 ha from the original pond design.

3.4 *Todd Pond and Clarke Pond Model Keeper Update Analysis / Update of Half Moon Bay South Subdivision Plan. Letter to David Schaeffer Engineering Limited*. J.F.Sabourin and Associates Inc. July 25, 2013.

This report includes a model keeper analysis update for the future Clarke Pond located west of the future Realigned Greenbank Road and north of Cambrian Road. This update includes revisions to the Clarke Pond minor and major system drainage boundaries resulting from changes associated with the detailed design of the Half Moon Bay South subdivision.

3.5 *Todd Pond Model Keeper Analysis Re-Assessment of Existing System Capacity*. J.F.Sabourin and Associates Limited. (April 2015). City of Ottawa.

In April 2015, JFSA confirmed that the Todd Pond has adequate water quality volume to achieve 80% TSS removal for its current tributary area and its 'interim' tributary area of ± 170 ha (including 29 ha of external rural drainage). JFSA also analysed an 'ultimate' drainage area scenario which included 5.6 ha of future developed lands within the BSUEA. The results of this analysis concluded that the Todd Pond would be able to accommodate this additional area if the outlet weir to the Jock River were to be extended.

3.6 *Site Servicing Report Quinn's Pointe 3872 Greenbank Road*. J.L. Richards and Associates Limited. (July 2015). Minto Communities Inc.

Quinn's Pointe is a residential subdivision currently being developed Minto located adjacent to the BSUEA at the south eastern boundary. The subdivision is bounded by Greenbank Road to the east and the Half Moon Bay South subdivision to the north. The Site Servicing Report was completed by J.L. Richards in 2015 and outlines the water supply, wastewater and stormwater servicing strategies for the site. The strategies are in general conformance with the Draft 2014 BSMSSA and the 2014 Stormwater Management Barrhaven South Report prepared by IBI which recommends the use of an on-site dry pond facility to capture major system flows rather than convey major system flows to the Todd Pond as per the original 2007 BSMSS.

3.7 *Thomas R. Baxter Municipal Drain Engineers Report*. Graham, Berman & Associates Ltd. (May 1967). Township of Nepean.

The Spence Branch of the Thomas R. Baxter Municipal Drain originates on the south side of Barnsdale Road on the southern boundary of the study area. The Engineer's Report for the municipal drain was completed in 1967 and recommended deepening and enlarging the main drain to a size sufficient to relieve flooding conditions along it with the necessary increases in the road culvert crossings. It was with this report that construction of the Spence Branch was recommended to relieve flooding conditions.

4.0 OTHER BACKGROUND REPORTS

4.1 *Final Geotechnical Investigation Proposed Barrhaven South Community 3872 Greenbank Road Ottawa*. Paterson Group Inc. (July 2014). Minto Communities Inc.

4.2 *Supplementary Geotechnical Assessment Proposed Quinn's Pointe Development Barrhaven South 3872 Greenbank Road – Ottawa. Letter to Minto Communities Inc*. Paterson Group Inc. May 19, 2015.

4.3 *Geotechnical Recommendations Greenbank Road Trunk Services Extension Quinn's Pointe Development - Ottawa. Letter to Minto Communities Inc*. Paterson Group Inc. July 23, 2015.

Geotechnical documents have been produced to support some of the infrastructure surrounding the site including reports for the Greenbank Road Trunk Services Extension, supplementary information for Quinn Pointe Subdivision, and the Barrhaven South Community to the west of the study area.

4.4 *Summary of the Jock River Reach 2 Subwatershed Existing Conditions*. City of Ottawa Land Use and Natural Systems Policy Group. (2011).

The subwatershed of reach 2 of the Jock River is upstream of Highway 416 and west of the BSUESA. The Existing Conditions report, prepared by the City of Ottawa in 2011, analysed various aspects of the subwatershed reach including climate, geology and physiography, surface and ground water hydrology and hydraulics, water quality and ecology and land use planning.

EXISTING CONDITION REPORT – APPENDIX B
SWMHYMO MODEL DESCRIPTION

MINTO COMMUNITIES INC. & MATTAMY HOMES LTD.
BARRHAVEN SOUTH URBAN EXPANSION AREA

1.0 NASHYD

In catchment areas with an area of impervious less than 20% the NASHYD command was used.

<table>
<tr><th>Parameter</th><th>Units</th><th>Description</th></tr>
<tr><td>Catchment Area</td><td>ha</td><td>The catchment area was delineated using the supplied contours and took account of quarries. In the Pre-development model no changes are made to the catchment areas but the pits are assumed to be filled to the surrounding ground level.</td></tr>
<tr><td>CN</td><td></td><td>The modified CN* value is used in the model. The CN values are based on hydrological soil types from OMAFRA mapping and MTO Design Chart 1.08 and land cover as per the aerial photography. The MTO drainage manual Design Chart 1.09 was used to assign CN values. The following CN values have been used:
<table>
<tr><th rowspan="2">Land Cover</th><th colspan="4">CN for Hydrologic Soil Group</th></tr>
<tr><th>A</th><th>AB</th><th>B</th><th>BC</th></tr>
<tr><td>Asphalt</td><td colspan="4">98</td></tr>
<tr><td>Agricultural</td><td>39</td><td></td><td>61</td><td>68</td></tr>
<tr><td>Grass</td><td>39</td><td></td><td>61</td><td></td></tr>
<tr><td>Gravel</td><td>76</td><td>81</td><td></td><td></td></tr>
<tr><td>Pasture</td><td>39</td><td>50</td><td></td><td>68</td></tr>
<tr><td>Pond/Lake</td><td colspan="4">50</td></tr>
<tr><td>Unimproved Lands</td><td>49</td><td></td><td></td><td></td></tr>
<tr><td>Woodlot</td><td>30</td><td></td><td>58</td><td></td></tr>
</table>
The CN values were area weighted for each catchment area.</td></tr>
<tr><td>Initial Abstraction</td><td>mm</td><td>Initial Abstraction values are 0.075S for areas with CN value less than 70 and 0.1S for areas with CN values greater than 70. (Visual Otthymo Manual)</td></tr>
<tr><td>Time to Peak</td><td>hrs</td><td>The time to peak is 0.6 of the Time of Concentration which was calculated using Uplands Method.</td></tr>
</table>

2.0 STANDHYD

In catchment areas with impervious greater than 20% of the area, the STANDHYD command was used.

Parameter	Units	Description
Catchment Area	ha	The catchment area was delineated using the supplied contours and took account of quarries. In the Pre-development model no changes are made to the catchment areas but the pits are assumed to be filled to the surrounding ground level.
Imperviousness		The total imperviousness (TIMP) was calculated from land cover based on the aerial photography. Lands that are sealed such as parking lots or roads are included as impervious. The directly connected imperviousness (XIMP) (the percentage of impervious surface not routed through a pervious surface) is negligible as there is no storm sewer network to collect the flow from these areas.
Horton Coefficients		Horton methods are used to calculate the infiltration. The Horton coefficients entered are from the City of Ottawa manual and are typical for the Ottawa area. The values are f_c = 13.2 mm/hr, f_o = 76.2 mm/hr, k = 0.0015 s^{-1}.
Initial Abstraction	mm	Initial abstraction values are as per the City of Ottawa drainage manual: 4.67 mm for pervious areas and 1.57 mm for impervious areas.
Slope	%	Slope was read from the contour data and averaged across the catchment area for the pervious slope parameter. The impervious slope parameter is based on the cross grade on a typical road section.
Flow Length	m	The pervious flow length is based on the longest flow path from contour data, the impervious flow length is half a typical road width.
Manning's n		The pervious Manning's n value is 0.25 to be representative of sheet flow through grassland or pasture. Impervious Manning's n value is 0.013 to be representative of an asphalt surfacing.

SUBJECT: Thomas Baxter Municipal Drain – Appointment of Engineer

OBJET: Drain municipal Thomas Baxter – Nomination d'un ingénieur

REPORT RECOMMENDATIONS

That the Agriculture and Rural Affairs Committee recommend that Council appoint Mr. Andy Robinson, P. Eng of Robinson Consultants Inc. as the engineer of record to prepare a report under Section 78 of the *Drainage Act* to inform Council on the drainage works project, if any, that is required to address the proposed residential subdivision that will outlet into the Thomas Baxter Municipal Drain.

RECOMMANDATIONS DU RAPPORT

Que le Comité de l'agriculture et des affaires rurales recommande au Conseil de nommer M. Andy Robinson, ingénieur de la firme Robinson Consultants Inc., comme ingénieur chargé de rédiger un rapport aux termes de l'article 78 de la *Loi sur le drainage*, afin d'informer le Conseil au sujet du projet de travaux de drainage, le cas échéant, nécessaire pour le lotissement résidentiel proposé dont les eaux pluviales se déverseront dans le drain municipal Thomas Baxter.

BACKGROUND

A developer of lands within the existing watershed of the Thomas Baxter Municipal Drain is proposing a new residential subdivision with stormwater management facilities that will outlet into the Dynes Branch of the Thomas Baxter Municipal Drain.

Staff therefore recommends that Council appoint an engineer to prepare a report under Section 78 of the *Drainage Act* to review proposed residential subdivision and the impact of the proposed establishment of stormwater management facilities within the watershed of the Thomas Baxter Municipal Drain, for Council's consideration.

DISCUSSION

Pursuant to Section 78 of the *Drainage Act*, a report of an Engineer, appointed by Council, is required to address land use changes and potential modifications within the watershed of the Thomas Baxter Municipal Drain. The Dynes Branch of the Thomas Baxter Municipal Drain is located in Rideau-Goulbourn Ward South of Barnsdale Road along Cedarview Road and Brophy Road and Highway 416 and was first constructed in 1967, under a report by Graham, Berman & Associates Ltd., by the former City of Nepean (now Rideau-Goulbourn Ward).

Proposed development within the existing legal watershed of the Thomas Baxter Municipal Drain requires a review and possible update to the 1967 Engineers Report to

reflect the proposed land use changes within the watershed of the drainage works, by a Council-appointed Drainage Engineer in accordance with Section 78 of the *Drainage Act*. A report under Section 78 of the *Drainage Act* will also include a review of the outlet for the surface, subsurface and stormwater management facility waters generated by the development lands.

The watershed of the Thomas Baxter Municipal Drain is adjacent to the watershed of the Hawkins Municipal Drain. The proposed development is assessed into both watersheds. The 1975 Engineers' Report for the Hawkins Municipal Drain is being updated under a separate staff report (ACS2016-COS-ESD-0023).

Staff are recommending the appointment of Mr. Andy Robinson, P.Eng. of Robinson Consultants Inc., as the engineer of record as he has over 40 years experience with similar *Drainage Act* projects, a specialized field of engineering in Ontario.

This report has no tax or budget implications. All costs associated with the engineer's report will be initially paid by the Surface Water Branch of the City but eventually recovered from the proponents. The estimated cost of the initial review by the Drainage Engineer is $25,000. Additional costs are expected if the Engineer determines that modifications and improvements to the drainage works are required. However, these would be assessed back to all benefiting landowners. Funding is available in the 2016 Approved Rate Supported Capital Budget, Municipal Drains Program.

The *Drainage Act* prescribes the process and timelines that must be followed for any modification or construction of a municipal drain.

Schedule for the Thomas Baxter Municipal Drain

Should the Agricultural and Rural Affairs Committee and Council approve the appointment of the Engineer, Mr. Andy Robinson P. Eng. of Robinson Consultants Inc., the anticipated schedule will be as follows:

- Council appointment of Engineer to prepare a report for Council's consideration – June 2016
- Preparation of engineer's report – June 2016 to December 2016
- Submission of engineer's report and staff report containing staff's recommendation to Council – December 2016
- Consideration of report and Council decision under Section 78 based on implications and evaluation in the engineer's report and staff's recommendation to Council – December 2016

- Court of Revision – January 2017
- Drainage Tribunal 40 day appeal period – Q1 of 2017

RURAL IMPLICATIONS

The proposed subdivision will benefit from this undertaking through improved drainage, storm water management and reduced risk of flooding.

CONSULTATION

Consultation with the Ward Councillors, and City staff is ongoing.

COMMENTS BY THE WARD COUNCILLOR(S)

The Ward Councillors are aware of this report.

LEGAL IMPLICATIONS

For the reasons that follow, there are no legal impediments to the implementation of the recommendation in this report.

The outlet for the surface, subsurface and stormwater management facility waters generated by the development lands is a drain that is subject to an existing engineer's report under the Drainage Act and the City has a legislated duty to maintain and repair all drains under Drainage Act (Sections 78 and 79 of the Drainage Act).

The City may be liable for any damages incurred by owners of land within the watershed of the Thomas Baxter Municipal Drain if the City fails to appoint an engineer under Section 78 of the *Drainage Act* to prepare a report evaluating whether the proposed change in use of lands justifies any improvements to the drainage works and/or a variation of the assessments for maintenance and repair of the drainage works under the 1967 Engineer's Report.

If the drainage engineer appointed under Section 78 reports that a drainage works project is required to address the proposed land use changes and establishment of stormwater management facilities within the watershed of the Thomas Baxter Municipal Drain, the existing 1967 drainage engineer's report will need to be updated and new schedules of assessment produced for the following:

i. the construction of the required improvements, and

ii. the future maintenance and repair of the drainage works.

RISK MANAGEMENT IMPLICATIONS

There are no risk implications associated with this report.

FINANCIAL IMPLICATIONS

This report has no tax or budget implications. The estimated cost of the initial review by the Drainage Engineer is $25,000. Additional costs are expected if the Engineer determines that modifications and improvements to the drainage works are required. However, these would be assessed back to all benefiting landowners. Funding is available in the 2016 Approved Rate Supported Capital Budget, Municipal Drains Program. Once approved by Council, a separate new internal order will be created for this specific drain and all necessary funding will be transferred to it.

ACCESSIBILITY IMPACTS

There are no accessibility impacts associated with this report.

ENVIRONMENTAL IMPLICATIONS

The drainage works are associated with final approval of the subdivision. Any proposed works will require compliance with City, provincial and federal policies, standards, regulations and legislation.

TERM OF COUNCIL PRIORITIES

The proposed drainage works will fulfill the City’s Strategic Plan’s environment and infrastructure protection priorities.

SUPPORTING DOCUMENTATION

RECOMMANDATIONS DU RAPPORT

Que le Comité de l'agriculture et des affaires rurales recommande au Conseil de nommer M. Andy Robinson, ingénieur de la firme Robinson Consultants Inc., comme ingénieur chargé de rédiger un rapport aux termes de l'article 78 de la *Loi sur le drainage*, afin d'informer le Conseil au sujet du projet de travaux de drainage, le cas échéant, nécessaire pour le lotissement résidentiel proposé dont les eaux pluviales se déverseront dans le drain municipal Hawkins.

BACKGROUND

A developer of lands within the existing watershed of the Hawkins Municipal Drain is proposing a new residential subdivision with stormwater management facilities that will outlet into Branch A of the Hawkins Municipal Drain.

Staff therefore recommends that Council appoint an engineer to prepare a report under Section 78 of the *Drainage Act* to review proposed the proposed residential subdivision within the Hawkins Municipal Drain watershed and the impact of the proposed establishment of stormwater management facilities that will outlet into the watershed of the Hawkins Municipal Drain, for Council's consideration.

DISCUSSION

Pursuant to Section 78 of the *Drainage Act*, a report of an Engineer, appointed by Council, is required to address land use changes and potential modifications within the watershed of the Hawkins Municipal Drain. The Hawkins Municipal Drain is located in Rideau-Goulbourn Ward east of Highway 416 near the intersection of Greenbank Road and Barnsdale Road and was first constructed in 1975, under a report by Kostuch Engineering Limited, by the former City of Nepean (now Rideau-Goulbourn Ward).

Proposed development within the existing legal watershed of the Hawkins Municipal Drain requires a review and possible update to the 1975 Engineers Report to reflect the proposed land use changes within the watershed of the drainage works, by a Council-

appointed Drainage Engineer in accordance with Section 78 of the *Drainage Act*. A report under Section 78 of the *Drainage Act* will also include a review of the outlet for the surface, subsurface and stormwater management facility waters generated by the development lands.

The watershed of the Hawkins Municipal Drain is adjacent to the watershed of the Thomas Baxter Municipal Drain. The proposed development is assessed into both watersheds. The 1967 Engineers' Report for the Thomas Baxter Municipal Drain is being updated under a separate staff report (ACS2016-COS-ESD-0024).

Staff are recommending the appointment of Mr. Andy Robinson, P.Eng. of Robinson Consultants Inc., as the engineer of record as he has over 40 years experience with similar *Drainage Act* projects, a specialized field of engineering in Ontario.

This report has no tax or budget implications. All costs associated with the engineer's report will be initially paid by the Surface Water Branch of the City but eventually recovered from the proponents. The estimated cost of the initial review by the Drainage Engineer is $25,000. Additional costs are expected if the Engineer determines that modifications and improvements to the drainage works are required. However, these would be assessed back to all benefiting landowners. Funding is available in the 2016 Approved Rate Supported Capital Budget, Municipal Drains Program.

The *Drainage Act* prescribes the process and timelines that must be followed for any modification or construction of a municipal drain.

Schedule for the Hawkins Municipal Drain

Should the Agricultural and Rural Affairs Committee and Council approve the appointment of the Engineer, Mr. Andy Robinson P. Eng. of Robinson Consultants Inc., the anticipated schedule will be as follows:

- Council appointment of Engineer to prepare a report for Council's consideration – June 2016
- Preparation of engineer's report – June 2016 to December 2016
- Submission of engineer's report and staff report containing staff's recommendation to Council – December 2016
- Consideration of report and Council decision under Section 78 based on implications and evaluation in the engineer's report and staff's recommendation to Council – December 2016
- Court of Revision – January 2017

- Drainage Tribunal 40 day appeal period – Q1 of 2017

RURAL IMPLICATIONS

The proposed subdivision will benefit from this undertaking through improved drainage, storm water management and reduced risk of flooding.

CONSULTATION

Consultation with the Ward Councillors, and City staff is ongoing.

COMMENTS BY THE WARD COUNCILLOR(S)

The Ward Councillors are aware of this report.

LEGAL IMPLICATIONS

For the reasons that follow, there are no legal impediments to the implementation of the recommendation in this report.

The outlet for the surface, subsurface and stormwater management facility waters generated by the development lands is a drain that is subject to an existing engineer's report under the *Drainage Act* and the City has a legislated duty to maintain and repair all drains under *Drainage Act* (Sections 78 and 79 of the *Drainage Act*).

The City may be liable for any damages incurred by owners of land within the watershed of the Hawkins Municipal Drain if the City fails to appoint an engineer under Section 78 of the *Drainage Act* to prepare a report evaluating whether the proposed change in use of lands justifies any improvements to the drainage works and/or a variation of the assessments for maintenance and repair of the drainage works under the 1975 Engineer's Report.

If the drainage engineer appointed under Section 78 reports that a drainage works project is required to address the proposed land use changes and establishment of stormwater management facilities within the watershed of the Hawkins Municipal Drain, the existing 1975 drainage engineer's report will need to be updated and new schedules of assessment produced for the following:

i. the construction of the required improvements, and

ii. the future maintenance and repair of the drainage works.

RISK MANAGEMENT IMPLICATIONS

There are no risk implications associated with this report.

FINANCIAL IMPLICATIONS

This report has no tax or budget implications. The estimated cost of the initial review by the Drainage Engineer is $25,000. Additional costs are expected if the Engineer determines that modifications and improvements to the drainage works are required. However, these would be assessed back to all benefiting landowners. Funding is available in the 2016 Approved Rate Supported Capital Budget, Municipal Drains Program. Once approved by Council, a separate new internal order will be created for this specific drain and all necessary funding will be transferred to it.

ACCESSIBILITY IMPACTS

There are no accessibility impacts associated with this report.

ENVIRONMENTAL IMPLICATIONS

The drainage works are associated with final approval of the subdivision. Any proposed works will require compliance with City, provincial and federal policies, standards, regulations and legislation.

TERM OF COUNCIL PRIORITIES

The proposed drainage works will fulfill the City’s Strategic Plan’s environment and infrastructure protection priorities.

SUPPORTING DOCUMENTATION

Document 1 – Location Plan

DISPOSITION

The Drainage Superintendent shall notify all affected landowners and the local conservation authority of the decision of Council.

APPENDIX 'B3'

WATER BUDGET ANALYSIS

EXISTING CONDITION REPORT – APPENDIX B3
PCSWMM WATER BUDGET MODEL DESCRIPTION

MINTO COMMUNITIES INC. & MATTAMY HOMES LTD.
BARRHAVEN SOUTH URBAN EXPANSION AREA

The tables below describe the parameters and values used for the water balance modeling in PCSWMM. In some cases values are required to be entered which, in this specific model scenario, are not used but must still be entered. Where a value does not affect the model or is not used the row is in grey.

1.0 CATCHMENTS

Parameter	Units	Description
Name	-	The name of the subcatchment. Format used is generally *Overland Outlet_Groundwater Outlet_Max Infiltration Value*.
Tag	-	The watercourse which the overland flow will discharge to.
Rain Gauge	-	The Storm used in the model simulation. In this case OTTRAIN is the name for the continuous simulation time series used.
Outlet	-	The downstream major system node to which the subcatchment drains
Area	ha	The area is calculated internally by PCSWMM
Width / Flow Length	m	Flow path lengths for the subcatchments were identified based on the GIS flow path analysis and the longest length through the subcatchment selected as the flow path. The width is then internally calculated in PCSWMM from the flow path length and drainage area.
Slope	%	Averaged from the GIS analysis of the LiDAR surface data.
Imperv	%	Area weighted value from the SWMHYMO model parameters.
N Imperv	-	A constant of 0.02 is selected as the Manning's N for impervious surfaces such as roads.
N Perv	-	A constant of 0.25 is selected as the Manning's N for pervious areas. The value is representative of light to tense turf land cover as per Table 3-5 of the EPA Storm Water Management Model Reference Manual Vol I – Hydrology (EPA, 2016).

Parameter	Units	Description
DStore Imperv	mm	A constant of 1.57 mm is used as the impervious depression storage as per the City of Ottawa Sewer Design Guidelines 2012 Section 5.4.5.4.
DStore Perv	mm	The value is area weighted from the SWMHYMO model parameters.
Zero Imperv	%	Used to represent areas where there is no depression storage in impervious areas such as water bodies. Not used in this model.
Subarea Routing	-	All catchments are completely drained to the outlet. The parameter would be used if any impervious areas were being drained via a storm sewer system.
Percent Routed	%	Used to determine the percent of sub-area being routed as per the parameter above. In this case 100% is going to the outlet.
Maximum Infiltration Rate	mm/hr	The maximum rate on the Horton Infiltration Curve, taken from the conversion of the Paterson field tested Hydraulic Conductivity values.
Minimum Infiltration Rate	mm/hr	The minimum rate on the Horton Infiltration Curve. This rate is based on the soil type assumed from the Paterson field testing.
Decay Constant	hr^{-1}	City of Ottawa standard value of 4.14 used.
Drying Time	days	The time for a fully saturated soil to completely dry is set at 7 days.
Maximum Volume	mm	The maximum volume of runoff which can be infiltrated and no limit has been applied in this model.

Curb length, LID Controls and Erosion parameters are not used in the model. Curb length relates to pollution control, there are no LID controls in the pre development scenario and there is no application of soil sediment loss in the model.

2.0 SNOWMELT

Parameter	Units	Description
Dividing Temperature	°C	The temperature below which precipitation will fall as snow. Generally accepted as being 0°C. **Value: 0**

Parameter	Units	Description
Snow Capture Factor	Fraction	It is assumed that the data from Environment Canada has captured all snowfall in the gauges. This factor can be used to increase snowfall where the gauges may not be accurate. **Value: 1.0**
ATI Weight	Fraction	Applied over the entire subwatershed, the ATI weighting factor is an indication of the thickness of the surface layer of snow. A low value will indicate a thicker surface layer with weighting to temperatures over the previous week while a value closer to 0.5 will indicate a normal surface layer. The lower the ATI Weight the snow will cool and warm more slowly. A value of 0.5 has been found to give reasonable results in watersheds and has been used here. **Value: 0.5**
Negative Melt Ratio	Fraction	The effect of the heat transfer during non-melt periods and the standard value is used. **Value 0.6**
Elevation above MS	m	The elevation will affect atmospheric pressure for the melt calculations. **Value: 107**
Latitude	°	The latitude will dictate the sunrise and sunset times in temperature calculations. **Value: 45.0**
Longitude Correction	minutes	Used to correct for in separation of the position of site versus the meridian of the standard time zone. This will have negligible effects. **Value: 0**
Melt Coefficients	mm/hr/°C	The Melt Coefficient has been taken from the AES snowmelt equations for southern Ontario (MNR Technical Guide Flooding Hazard Limit, 2002). The AES equations have a melt coefficient of 3.66 mm/day/°C for mean daily air temperatures. This equates to 0.1525 mm/hr/°C. **Value: 0.153**
Base Temperature	°C	The base temperature at which the snowpack will melt has been assumed as 0°C. A lower value could be used for rooftops where there will be heat transfer through the roof. **Value: 0**

Parameter	Units	Description
Fraction Free Water Capacity	Fraction	Since snow is considered a porous medium some of the melt water may be contained within the snow pack. The fraction of the free water capacity is the fraction of the snow pack void space which will retain meltwater. This fraction is normally less than 0.1 and 0.05 has been used here to represent a deep snowpack. A value of 0.25 may represent a shallow slush layer. **Value: 0.05**
Initial Snow Depth	mm	The initial snow depth on the site is considered as zero. **Value: 0**
Initial Free Water	mm	Since there is no initial snow depth the initial free water has also been considered as zero. **Value: 0**
Depth at 100% Cover	mm	The snowmelt model assumes that there will always be a depth of snow above which there will be 100% coverage of the snow, even in areas which may be affected by shading, drifting of topography. Typical depths are 25 mm to 100 mm. Since the area is relatively open with limited shading then the lower end of the value range has been used. **Value: 25**
Areal Depletion	Fraction	The areal depletion curve represents the area of snow cover for depths of the snow less than the depth at 100% coverage. Natural areal depletion curves are suggested by the software and are used here.

No parameters were used related to mechanical snow removal as it is assumed that there are no snow removal operations on the BSUEA currently.

3.0 GROUNDWATER

3.1 Groundwater Parameters

<table>
<tr><th>Parameter</th><th>Units</th><th>Description</th></tr>
<tr><td>Aquifer Name</td><td>-</td><td>Name of the aquifer representing soil conditions. Four Aquifers were created based on different soil conditions from OSG mapping. Only two of the aquifers are used within the study area.
<table>
<tr><th>Aquifer</th><th>Description</th><th>Clay content (%)</th><th>Sand content (%)</th></tr>
<tr><td>A</td><td>Sand</td><td>5</td><td>92</td></tr>
<tr><td>B</td><td>Sandy Loam</td><td>10</td><td>65</td></tr>
<tr><td>C (not used)</td><td>Sandy Clay Loam</td><td>28</td><td>60</td></tr>
<tr><td>D (not used)</td><td>Clay Loam</td><td>34</td><td>33</td></tr>
</table></td></tr>
<tr><td>Receiving Node</td><td>-</td><td>Name of the receiving node for groundwater outflow to baseflow. This is based on the groundwater subwatershed delineation.</td></tr>
<tr><td>Surface Elevation</td><td>m</td><td>Elevation of the ground surface for the subcatchment was averaged from the Patterson report.
Value: 107</td></tr>
<tr><td>Coefficients</td><td></td><td>The coefficients were set for the saturated groundwater zone to represent a storage reservoir where outflow is linear proportional to the water table depth without surface water interaction. It was considered that the nearest open water channels were sufficiently far to have negligible impact on groundwater levels. The groundwater equation used is:
$f_G = A1\ (d_L - h_{sw})$
Where:
f_G = groundwater flow
d_L = depth of the lower saturated subsurface zone
h_{sw} = height of surface water above the bottom of the groundwater zone
A1 = Calibration factor (estimated at 0.05)
Value: 0.05</td></tr>
<tr><td>Surface Water Depth</td><td>m</td><td>Set as 0.5 metres to allow flow from the water table to surrounding watercourses.
Value: 0.5</td></tr>
</table>

Parameter	Units	Description
Initial Elevation	m	Initial elevation of the water table **Value: 95.5**
		All other parameters used as per the receiving node or aquifer

3.2 Aquifer Parameters

Parameter	Units	Description / Values
Porosity	Fraction	The following values were used for the volumetric water content of the soil at saturation (i.e. volume of water per total volume): **Soil Group** / **A** / **B** / **C** / **D** Porosity / 0.436 / 0.450 / 0.432 / 0.472 *(Source: SPAW Calculator)*
Wilting Point	Fraction	This is soil moisture contact at which plants cannot obtain sufficient moisture from the soil to meet transpiration requirements and they will die. It is roughly equivalent to the moisture content of soil at 15 atmospheres. The following values were used: **Soil Group** / **A** / **B** / **C** / **D** Wilting Point / 0.050 / 0.081 / 0.183 / 0.213 *(Source: SPAW Calculator)*
Field Capacity	Fraction	Considered to be the amount of water a well-drained soil holds after free water has drained off. The following values were used: **Soil Group** / **A** / **B** / **C** / **D** Field Capacity / 0.094 / 0.179 / 0.283 / 0.350 *(Source: SPAW Calculator)*
Conductivity	mm/hr	Within the Aquifer Parameters, the soil saturated conductivity is a governing parameter of the percolation rate between the upper unsaturated soil layer and the lower saturated soil layer. This is not the same as any hydraulic conductivity used for the surface infiltration. The values have been selected from the SPAW calculator and are: **Soil Group** / **A** / **B** / **C** / **D** Conductivity (mm/hr) / 114 / 50.3 / 7.8 / 4.6 *(Source: SPAW Calculator)*

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Conductivity Slope</td><td>-</td><td>Conductivity slope measures the rate at which a soil's hydraulic conductivity decreases with decreasing moisture content. Regression analysis has shown it can be estimated with the following relationship:

Conductivity Slope = 0.48(% Sand) + 0.85(% Clay)

Based on this relationship the following values were used:

<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Conductivity Slope</td><td>48</td><td>40</td><td>53</td><td>45</td></tr>
</table>
</td></tr>
<tr><td>Tension Slope</td><td></td><td>Used for backward compatibility in the software and not used in this model</td></tr>
<tr><td>Upper Evaporation Factor</td><td>Fraction</td><td>This factor determines the fraction of available subsurface evaporation rate used in the upper subsurface zone (compared to the lower subsurface zone). A higher evaporation rate is associated with looser soils, lower water table elevations and shallow root zones. It was assumed that in all soils 80% of the available subsurface evaporation would be used in the upper zone due to the depth of the water table.

Value: 0.8</td></tr>
<tr><td>Lower Evaporative Depth</td><td>m</td><td>The depth of the lower subsurface zone which can be used for evapotranspiration should be approximate to the expected average depth of root penetration. The following values were used:

<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Evaporative Depth (m)</td><td>1.5</td><td>2.4</td><td>3.0</td><td>5.2</td></tr>
</table>
(Source: Shah et al 2007 from EPA 2015)</td></tr>
<tr><td>Lower Groundwater Loss Rate</td><td>mm/hr</td><td>This is the rate of percolation from the lower subsurface zone to a deep aquifer and is approximate to the rate at which the water table elevation will drop over a prolonged dry period. The saturated hydraulic conductivity of a compacted clay soil was used in all cases.

Value: 0.004</td></tr>
<tr><td>Bottom Elevation</td><td>m</td><td>The elevation of the bedrock as averaged from the Patterson 2016 report.

Value: 85</td></tr>
</table>

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Unsaturated Zone Moisture</td><td></td><td>The moisture content of the unsaturated upper subsurface zone at the start of the simulation. Cannot be less than the wilting point and cannot be more that porosity. Assumed to be an approximate value between the wilting point and porosity fractions.
<table>
<tr><th>Soil Group</th><th>A</th><th>B</th><th>C</th><th>D</th></tr>
<tr><td>Evaporative Depth (m)</td><td>0.25</td><td>0.22</td><td>0.32</td><td>0.35</td></tr>
</table>
</td></tr>

SB-6 Percolation Time and Soil Descriptions

ESTIMATION OF PERCOLATION TIME

(a) The purpose of this Section and the associated Tables and Charts is to provide assistance to those who must decide on the percolation time(s) to be used in design. Suggested relationships between percolation time, coefficient of permeability and soils of various types are given. IT MUST BE EMPHASIZED THAT, PARTICULARLY FOR FINE GRAINED SOILS, THERE IS NO CONSISTENT RELATIONSHIP DUE TO THE MANY FACTORS INVOLVED. The following guidance is presented for the soil types outlined in the Unified Soil Classification System (Table 1). In order to assess a particular soil.
  (i) Table 2 and Table 3 - Approximate relationship of soil types to permeability and percolation time.
  (ii) Charts 1 to 14 - Typical grain size distribution curves for soil types in the Unified Soil Classification System.

(b) In Table 2 and Table 3, a range of values of "K" and of "T" are given for various soil descriptions. The principal modifiers which will influence selection of a "T" value within the range given are:
  (i) The structure - "massive" fine-grained soils have high values of "T".
  (ii) The density - For a given soil higher density produces a higher value of "T".
  (iii) The percentage of clay - the higher the percentage the higher the value of "T".
  (iv) The mineralogy of the clay portion - The more it "swells" the higher the value of "T".
  (v) The plasticity of the soil - The higher the plasticity index the higher the value of "T".
  (vi) Liquid Limit - the higher the liquid limit the higher the value of "T".
  (vii) Organic content - The presence of fine organic particles, detectable by colouration and odour, can significantly reduce the permeability and raise the value of "T".

Table 1
Unified Soil Classification

Coarse - Grained Soils		Fine - Grained Soils	
Group Symbols	Typical Names	Group Symbols	Typical Names
GW	Well-graded gravels, gravel-sand mixtures, little or no fines	ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity
GP	Poorly-graded gravels, gravel-sand mixtures, little or no fines	CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays
GM	Silty gravels, gravel-sand-silt mixtures	OL	Organic silts and organic silty clays of low plasticity
GC	Clayey gravels, gravel-sand-clay mixtures	MH	Inorganic silts, micoceous or diatomaceous fine sandy or silty soils, elastic silts
SW	Well-graded sands, gravelly sands, little or no fines	CH	Inorganic clays of high plasticity, fat clays
SP	Poorly-graded sands, gravelly sands, little or no fines	OH	Organic clays of medium to high plasticity, organic silts
SM	Silty sands, sand-silt mixtures		
SC	Clayey sands, sand-clay mixtures	PT (highly organic soils)	Peat and other highly organic soils
Column 1	2	3	4

Table 2
Approximate Relationship of Coarse Grained Soil Types to Permeability and Percolation Time

Soil Type (Unified Soil Classification) Coarse Grained More than 50% Larger than #200	Coefficient of Permeability, K - cm/sec	Percolation Time, T - mins/cm	Comment
G.W. - Well graded gravels, gravel-sand mixtures, little or no fines.	10^{-1}	<1	very permeable unacceptable
G.P. - Poorly graded gravels, gravel-sand mixtures, little or no fines.	10^{-1}	<1	very permeable unacceptable
G.M. - Silty gravels, gravel-sand-silt mixtures.	10^{-2} - 10^{-4}	4 - 12	Permeable to medium permeable depending on amount of silt.
G.C. - Clayey gravels, gravel-sand-clay mixtures.	10^{-4} - 10^{-6}	12 - 50	Important to estimate amount of silt and clay
S.W. - Well graded sands, gravelly sands little or no fines.	10^{-1} - 10^{-4}	2 - 12	medium permeability
S.P. - Poorly graded sands, gravelly sand, little or no fines.	10^{-1} - 10^{-3}	2 - 8	medium permeability
S.M. - Silty sands, sand-silt mixtures.	10^{-3} - 10^{-5}	8 - 20	medium to low permeability
S.C. - Clayey sands, sand-clay mixtures.	10^{-4} - 10^{-6}	12 - 50	medium to low permeability depending on amount of clay
Column 1	2	3	4

Table 3
Approximate Relationship of Coarse Grained Soil Types to Permeability and Percolation Time

Soil Type (Unified Soil Classification) Fine Grained More than 50% Passing #200	Coefficient of Permeability, K - cm/sec	Percolation Time, T - mins/cm	Comment
M.L. - Inorganic silts and very fine sands, rock flour, silty or clayey fine sands, clayey silts with slight plasticity	10^{-5} - 10^{-6}	20 - 50	medium to low permeability
C.L. - Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays	10^{-6} and less	over 50	unacceptable
O.L. - Organic silts, organic silty clays of low plasticity; liquid limit less than 50	10^{-5} and less	20 - over 50	acceptable depends on clay content
M.H. - Inorganic silts, micareaous or diatomageous fine sandy or silty soils, elastic silts	10^{-6} and less	over 50	unacceptable
C.H. - Inorganic clays of medium to high plasticity, organic silts	10^{-7} and less	over 50	unacceptable
O.H. - Organic clays of medium to high plasticity organic silt; liquid limit over 50	10^{-6} and less	over 50	unacceptable
Column 1	2	3	4

SELECTION OF "T" TIME FROM THE ABOVE TABULATION

A range of "T" times for each soil type is shown above. Select from within this range by determining if the soil is within the low, middle or high part of the range considering the soil identifiers and soil characteristics. Consider structure, density, colour, prevalence or organics, the clay content and mineralogy, the plasticity index and liquid limit and the functioning of existing systems in similar soils in the area.

Notes:

The following Ministry of the Environment Reports provide further information on the relationship between grain size, coefficient of permeability and percolation time.

1. "Study on the Feasibility of Correlating Percolation Time with Laboratory Permeability" - 1975 - Research Report No. S56 by H. T. Chan, PhD., P.Eng.

2. "Study of Conventional Tile Fields in Fine-Grained Soils" - 1979 Research Report 74 by H. T. Chan, PhD., P.Eng.

Horton Equation

One of the oldest and most widely used infiltration equations was developed by Horton (1939). This equation was used in this study to compare the measured equation parameters with published literature values. The equation is as follows:

$$f = f_c + (f_o - f_c)e^{-kt} \quad (1\text{-}1)$$

where:
f= infiltration capacity (in/hr),
f_o = initial infiltration capacity (in/hr),
f_c = final infiltration capacity (in/hr),
k = empirical constant (hr^{-1})

This equation assumes that the rainfall intensity is greater than the infiltration capacity at all times and that the infiltration rate decreases with time (Bedient and Huber 1992). The capacity of the soil decreases as the time of the storm increases because the pores in the soil become saturated with water and do not allow water to continuously infiltrate through the surface (Bedient and Huber 1992). The Horton equation's major drawback is that it does not consider storage availability in the soil after varying amounts of infiltration have occurred, but only considers infiltration as a function of time (Akan 1993).

It is recommended that f_c, f_o, and k all be obtained through field data, but they are rarely measured locally. More commonly, they are determined through calibration of relatively complex stormwater drainage models, or by using values published in the literature. The use of published values in place of reliable field data is the cause of much concern by many (Akan 1993). The following lists include commonly used Horton infiltration parameter values:

Soil Type	f_o (in/hr)
Dry sandy soils with little to no vegetation	5
Dry loam soils with little to no vegetation	3
Dry clay soils with little to no vegetation	1
Dry sandy soils with dense vegetation	10
Dry loam soils with dense vegetation	6
Dry clay soils with dense vegetation	2
Moist sandy soils with little to no vegetation	1.7
Moist loam soils with little to no vegetation	1
Moist clay soils with little to no vegetation	0.3
Moist sandy soils with dense vegetation	3.3
Moist loam soils with dense vegetation	2
Moist clay soils with dense vegetation	0.7

Soil Type	f_c mm/hr	(in/hr)	k (1/min)
Clay loam, silty clay loams	0–1.3	(0–0.05)	0.069
Sandy clay loam	1.3–3.8	(0.05–0.15)	0.069
Silt loam, loam	3.8–7.6	(0.15–0.30)	0.069
Sand, loamy sand, sandy loams	7.6–11.4	(0.30–0.45)	0.069

Source: Akan 1993.

The above k values are not divided into categories, with only a single value used for all conditions (Akan 1993). The units of the k value are listed as 1/min instead of 1/hr because the time steps commonly used in urban hydrology are measured in minutes, while the infiltration rates are commonly measured in units of inches per hour. These values will be compared to the measured values obtained during this study by calibrating the Horton equation.

APPENDIX 'B4'

WASTEWATER SERVICING

Existing `Critical' Downstream Sanitary Sewers

Area:

BARRHAVEN SOUTH
MASTER SERVICING STUDY

DATE: 11/28/2014
REVISION: 1
DESIGNED BY: LP
CHECKED BY: DT

SANITARY SEWER DESIGN SHEET
(City of Ottawa)

FILE NUMBER: 163400999

Colour code:
Hard coded values
Caculated value
Value from subdivision design
Most US MH
Estimated value
MH receiving flow from 2 or more sewers

DESIGN PARAMETERS

MAX PEAK FACTOR (RES.)=	4.0	AVG. DAILY FLOW / PERSON	350 L/p/day	MINIMUM VELOCITY	0.60 m/s	As per CDP (units/ha)	
MIN PEAK FACTOR (RES.)=	2.0	COMMERCIAL	50,000 L/ha/day	MAXIMUM VELOCITY	3.00 m/s	LOW DENSITY RESIDENTIAL	26
PEAKING FACTOR (INDUSTRIAL):	2.4	INDUSTRIAL (HEAVY)	55,000 L/ha/day	MANNINGS n	0.013	SEMI-DETACHED	52
PEAKING FACTOR (COMM., INST.):	1.5	INDUSTRIAL (LIGHT)	35,000 L/ha/day	BEDDING CLASS	B	TOWN HOUSES	82
PERSONS / SINGLE UNIT	3.4	INSTITUTIONAL	50,000 L/ha/day	MINIMUM COVER	2.50 m	APARTMENTS	120
PERSONS / TOWNHOME	2.7	INFILTRATION	0.28 L/s/ha			COMMUNITY CORE	60
PERSONS / APARTMENT	1.8					AVERAGE PERSONS/ha	107

Cambrian:
51.4 L/s res. cap

River Mist:
17.8 L/s res. cap*

Greenbank:
295.4 L/s res. cap

*Note that Quinn's Pointe (JLR, 2015) conveys 3.4 L/s additional flow to River Mist sewer than was originally allocated as part of the 2014 Draft BSMSSA
Therefore, residual capacity MH 102A - MH117A = 17.8 L/s - 3.4 L/s = 14.4 L/s

Refer to Stantec Sanitary Sewer System (FIG 3-5), for critical sanitary sewer locations

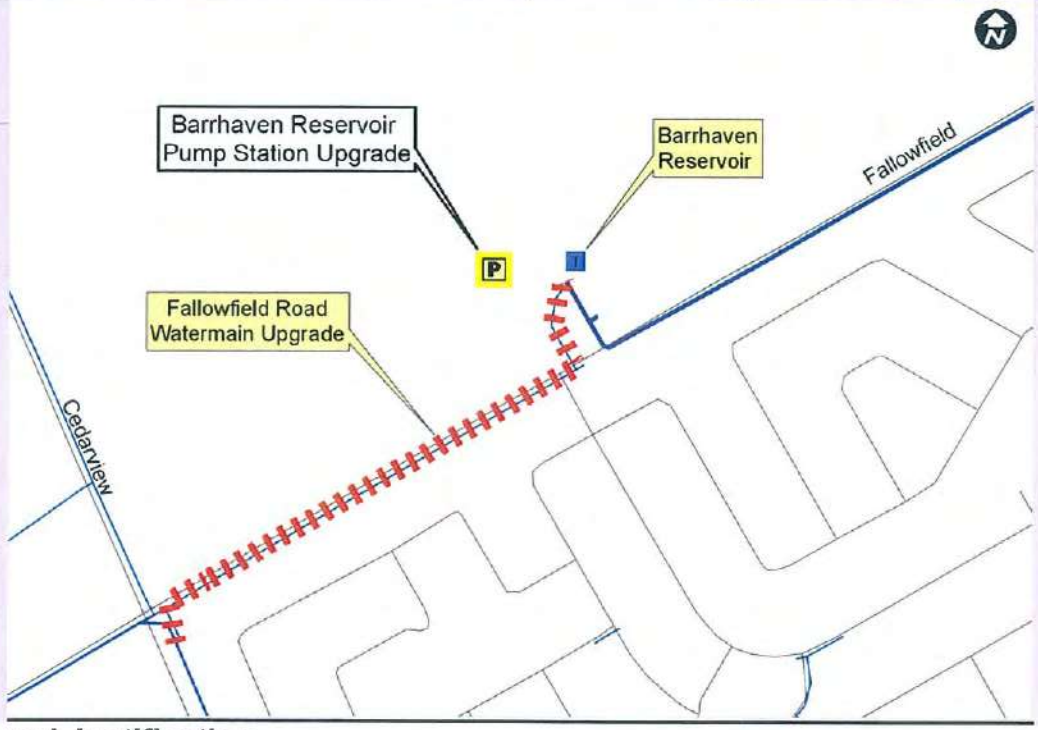
ORIGINAL SHEET - ISO A1

Barrhaven Reservoir Pump Station (BRPS) Upgrade



Scope and Justification

Increase pumping capacity and provide back-up powerat the BRPS (to Zone BARR) to provide adequate back-up and peaking supply demands to Zone BARR.

Timing

2013-2018: Complete upgrades to the BRPS

Action Item Funding

Construction Cost Estimate = $0.6M
Capital Cost Estimate* = $1.2M (90% Development Charges, 10% Rate)
**including construction cost, engineering, city internal costs and contingency allowance. Funding split subject to review as part of 2014 Development Charges by-law.*

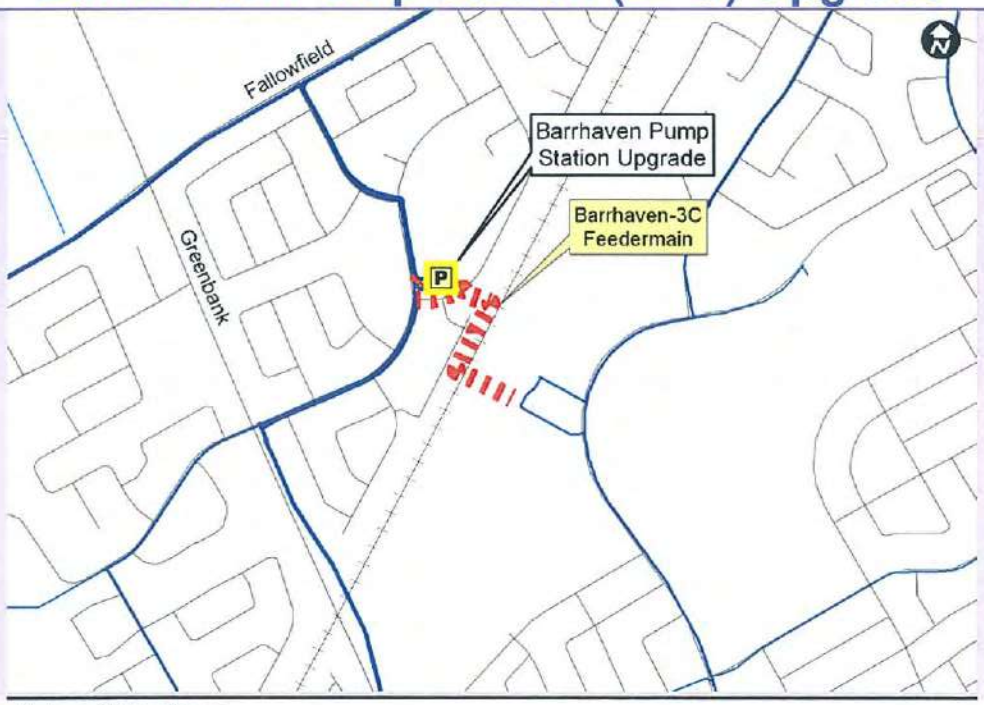
EA Requirements and Consultation

Class EA Schedule 'A' project. No consultation required prior to implementation.

Follow Up Actions

Review future capacity needs at the design stage to confirm the increase required. Coordinate with Fallowfield watermain project (needed to provide adequate station discharge capacity).

Barrhaven Pump Station (BPS) Upgrade



Scope and Justification

Reconfigure BPS to provide dual zone service (3C and BARR). Replace all pumping units to contribute to 2031 peak demand and back-up supply requirements for Zone 3C and Zone BARR. Upgrade back-up power.

Timing

2013-2018: Reconfigure and upgrade station (Phase 1)
2019-2024: Zone 3C capacity increase (Phase 2)

Action Item Funding

Phase 1 Construction Cost Estimate = $1.7M
Phase 1 Capital Cost Estimate* = $3.5M (90% Development Charges, 10% Rate)
Phase 2 Construction Cost Estimate = $0.3M
Phase 2 Capital Cost Estimate* = $0.6M (90% Development Charges, 10% Rate)
**including construction cost, engineering, city internal costs and contingency allowance. Funding split subject to review as part of 2014 Development Charges by-law.*

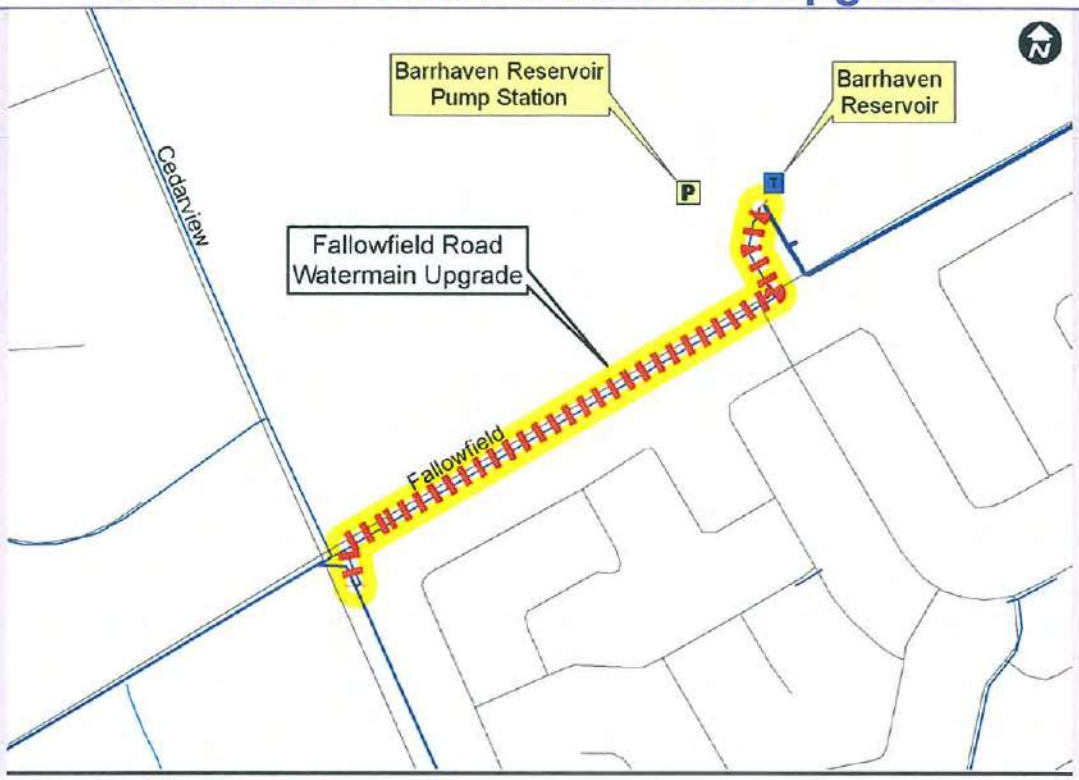
EA Requirements and Consultation

Class EA Schedule 'A' project. No consultation required prior to implementation.

Follow Up Actions

Review future capacity needs at the design stage to confirm the increase required. Coordinate works with 2017 electrical renewal.

Fallowfield Road Watermain Upgrade



Scope and Justification

Construct 406 mm watermain along Fallowfield Rd. from Barrhaven Reservoir to Cedarview Rd. to increase effective discharge capacity available for the Barrhaven Reservoir Pump Station (BRPS). The capacity increase is needed to support growth and reliability requirements for Zone Barr.

Timing

2013-2018: Construct watermain

Action Item Funding

Construction Cost Estimate = $0.7M
Capital Cost Estimate* = $1.3M (90% Development Charges, 10% Rate)
**including construction cost, engineering, city internal costs and contingency allowance. Funding split subject to review as part of 2014 Development Charges by-law.*

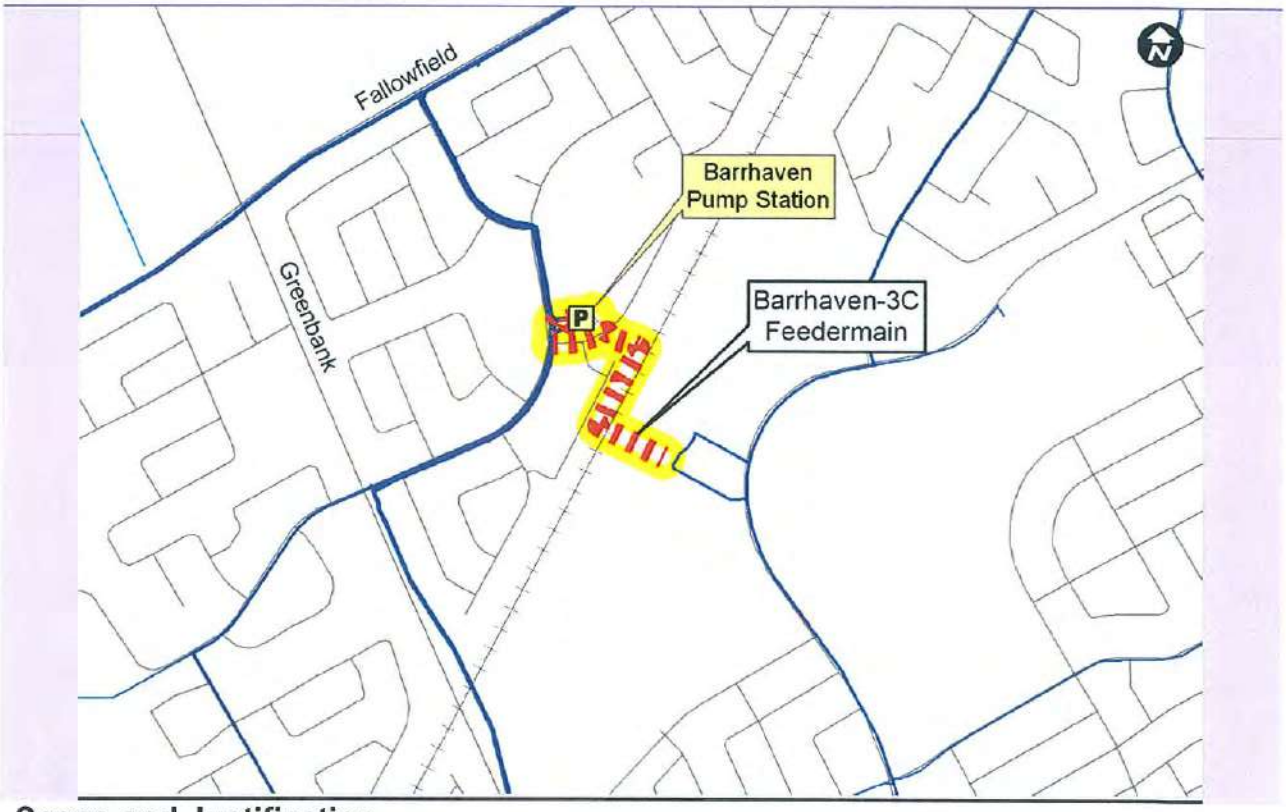
EA Requirements and Consultation

This is a Schedule 'A' project – No consultation required prior to implementation.

Follow Up Actions

Coordinate with BRPS upgrade.

Barrhaven-3C Feedermain



Scope and Justification

Construct 610 mm watermain from Foxfield at Holitman, across rail line and Transitway to Via Chianti Grove. The feedermain is needed to facilitate the zone reconfiguration and to meet 2031 growth and reliability requirements.

Timing

2013-2018: Construct feedermain

Action Item Funding

Construction Cost Estimate = $2.0M
Capital Cost Estimate* = $2.5M (90% Development Charges, 10% Rate)
**including construction cost, engineering, city internal costs and contingency allowance. Funding split subject to review as part of 2014 Development Charges by-law.*

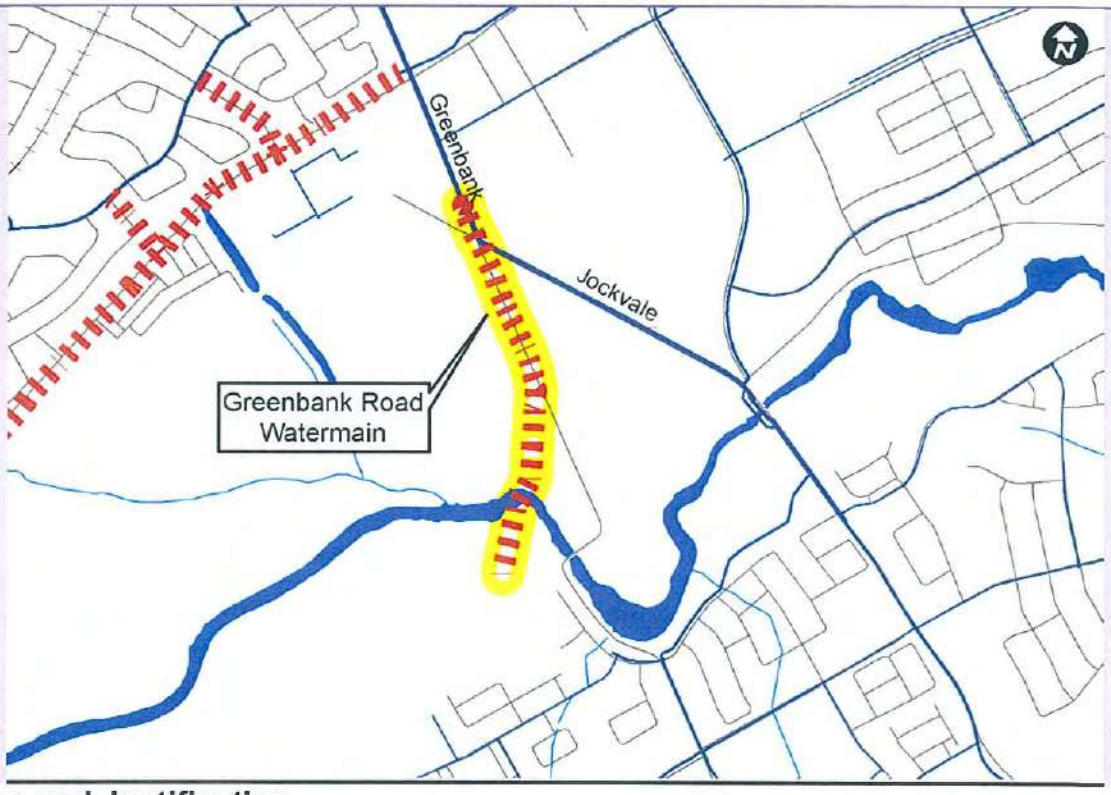
EA Requirements and Consultation

This is a Schedule 'A' project – No consultation required prior to implementation.

Follow Up Actions

Verify provisions needed for short term operations prior to Barrhaven Pump Station upgrade.

Greenbank Road Watermain



Scope and Justification

Construct 610 mm watermain along Greenbank Rd. from North of Jockvale to South of Jock River. This project is needed to support development south of the Jock River.

Timing

2013 – 2018 Construct feedermain

Action Item Funding

Construction Cost Estimate = $3.9M

Capital Cost Estimate* = $7.4M (90% Development Charges, 10% Rate)

**including construction cost, engineering, city internal costs and contingency allowance. Funding split subject to review as part of 2014 Development Charges by-law.*

EA Requirements and Consultation

This is a Schedule 'B' project as it requires a major water crossing – Notices, consultation and filing of Environmental Project File for public review required.

Follow Up Actions

Coordinate project with growth needs. Finalize alignment as part of detailed planning and design process.

HORIZONTAL SCALE 1:2000

EXISTING FEATURES

The entrance/exit is off Cedarview Road. There is a licensed pit directly adjacent to the north (George Drummond). There is a common boundary agreement on file with M.N.R.. There is a fair to good post and wire fence along this boundary. The west boundary has a post and wire fence in fair to very poor condition. There is an existing post and wire fence along the south boundary in poor condition. There is an electric, single strand fence, just outside the east boundary, used to keep cattle away.

The Regional Municipality of Ottawa Carleton operate the land-fill site to the west. The property to the south are vacant fields. The fields to the east are used for pasturing cattle.

The easterly portion of the south boundary is presently being backfilled with clean material excavated from construction sites off the property. It is being backfilled to the original ground elevation and width to restore the setback in that area and then sloped.

Rehabilitation has already begun along the east face.

Surface drainage is via natural seepage into the granular sub-base.

The scale house and maintenance building are located on part of the 30 metres setback along the south boundary.

There are several stockpiles of peat located behind the scale house and maintenance building. Several small stockpiles of topsoil are located in the northeast area of the licensed property.

To establish the water elevation of ±95.0 meters we have utilized information from test hole data rather than the data from M.O.E. well records.

OPERATION PLAN

Portable equipment will be used on the site and will include trucks, bulldozers, front-end loaders, and screening equipment and will be moved as needed around the site.

A new berm will be constructed along the newly located west boundary during the construction of Highway 416 in the summer/fall of 1992. The berm will be approximately 5.5 metres high and width of approximately 23 metres with 2:1 slope. Berm will be topsoiled and seeded to prevent erosion. A new post and wire fence will be placed along the western boundary. Two double sets of farm gates will go at the two entrances/exits as shown on the plan.

The existing fence along the south boundary adequately marks this area.

Gravel is located on the easterly half of the site. Most of the sand is located on the remaining west half of the property. Generally the pit will operate from an east to west direction, however, sand is being removed from the western part at the same time, at a higher elevation. The excavation for the most part will be carried out in 2 lifts to a final floor elevation of 90.0 metres. Lift 1 will mine down to approximately 1 metre above the water table at 95.0 metres. Material below the water will be removed using a hihoe. This operation above and below the water may be carried out simultaneously.

The area below water will be backfilled to an elevation approximately 2 metres above the water table (97.0 metres). Backfilling will follow operations as closely as possible in order that final rehabilitation can be completed progressively.

Minor Site Plan Amendment
Lic. 4219, Marcel Brazeau Ltd., Lot 8, Con. III, Nepean. Manufacturing of topsoil for resale and rehabilitation needs permitted on site. 46,000 m3 of topsoil will be produced and/or retained by the year 2011 for rehabilitation purposes. The rehabilitation topsoil will be stored in the berm along Cedarview Rd. and in a stockpile in the southwest corner of the site.

HORIZONTAL SCALE 1:2000

REHABILITATION

The backfill will be imported onto the site from excavated material from construction sites or other clean fill from ditching.

The north face will be backfilled to meet the final floor of the adjacent pit (104 metres). Most of the east face, except the south east corner, has been sloped.

The backfilling of the open water will commence at the east end once the operation has progressed sufficiently west so that product below water is not contaminated by the backfill.

When enough area has been backfilled to above water, it will be topsoiled/seeded to reduce the open area requiring rehabilitation as quickly as possible. The area will be seeded with a grass/legume mixture suitable for the backfilled material. It will be maintained to ensure healthy growth.

All pit faces will be sloped to a 3:1 gradient, topsoiled, and seeded.

The drainage will continue as seepage into the subsoil. The property will remain as a grassy field. Future use will be determined by the City of Nepean at a later date.

EXISTING FEATURES

Property licenced for pit operation as designated under the authority of the Aggregate Resources Act 1989.

A pit area presently exists on the majority of the licenced area. Natural drainage of the property is by seepage into the soil and surface drainage to the east.

A weigh scale, garage, office and barn all present on the site near the entrance/exit to the pit.

Fencing is not required along the north boundary. Fencing and setback is not required along the south boundary as there exists a boundary agreement between Brazeau and George W. Drummond Ltd., owners of the two properties in concern.

There is no setback along the west boundary as the adjacent property is owned by George Drumond.

A tree plantation of 7 year old Scots pine exists on the licenced property located at the east end. This area has been leased out by Drumond until 2002.

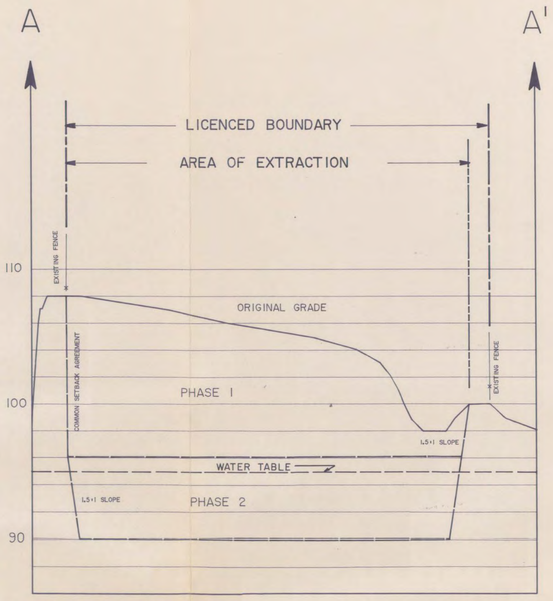
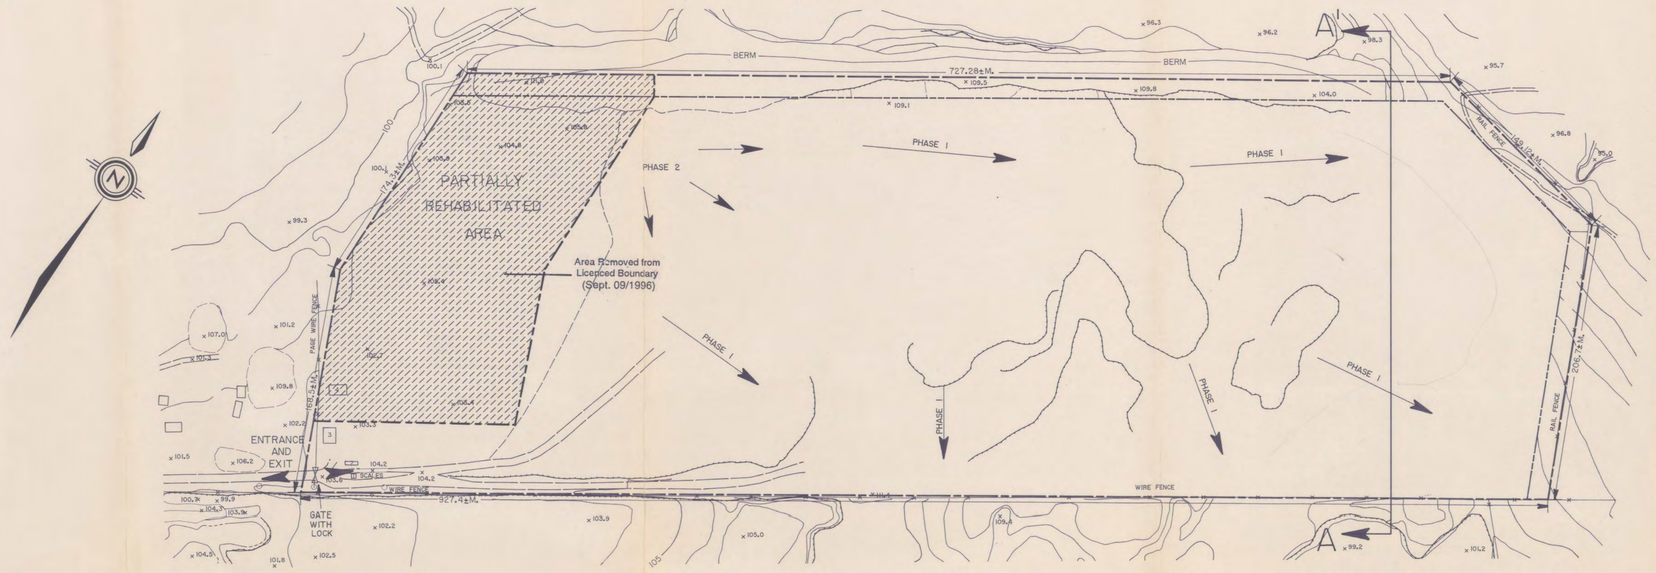
D. Lebrasseur
SEP 10 1996

OPERATION PLAN



HORIZONTAL SCALE - 2000

VERTICAL SCALE - 200



GENERAL

The pit will operate in accordance with the Aggregate Resources Act 1989.

Fencing and setback is not required along the south limits of the pit as agreed upon by Marcel Irazeau (pit owner to the south of Drummond) and George W. Drummond Ltd. Fencing is also not required for the north boundary. Various locations, where fences need not be established, have been agreed upon by the Ministry of Natural Resources.

The entrance/exit to the pit has a gate with a lock on it.

The entrance/exit to the pit is from Cedarview Road.

There exists no limitations to the types or location of excavation equipment which may operate on the site. All machinery is equipped with noise and dust suppressors.

Information pertaining to water wells is indicated on the Existing Features Plan.

Product stockpiles are stored within the confines of the limit of extraction.

Recycling of asphalt is permitted within the extraction limits. Area for recycling will be kept 10 metres from any open water.

The tree plantation area lease, upon its expiry date, will be subject to mining activity. Operation of this area will fall into regular mining phases as described within the Operation notes.

OPERATION

The licenced pit hectarage will be mined in two phases of operation. Phase 1 above water table, Phase 2 below water table.

Phase 1 mining is active, operating to a depth of approximately 95 metres as indicated on the Operation Plan. Direction of operation moves from the west towards the east.

Phase 2 mining will follow the Phase 1 mining pattern beginning from the westerly limits of the licenced property and proceeding in a easterly direction, as indicated on the Operation Plan.

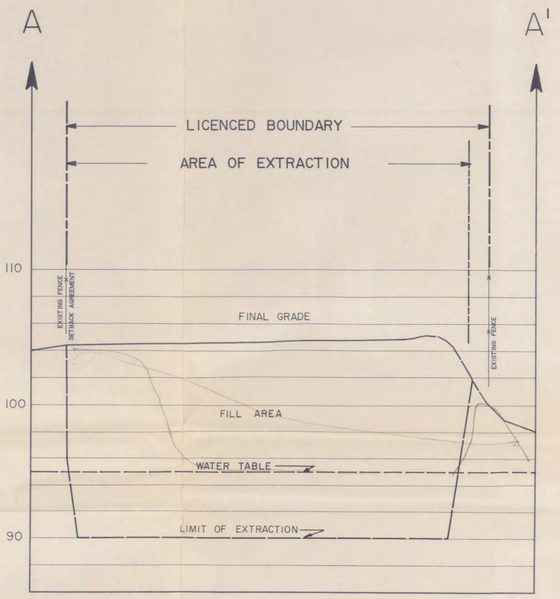
Phase 2 will begin mining operation upon completion of Phase 1. Mining will be below the water table. Extraction of the material will be by dragline methods. No pumping or letting of water will be needed. Final operation depth will be approximately 90 metres.

Amendment - April 29/99

Import topsoil to process for resale.

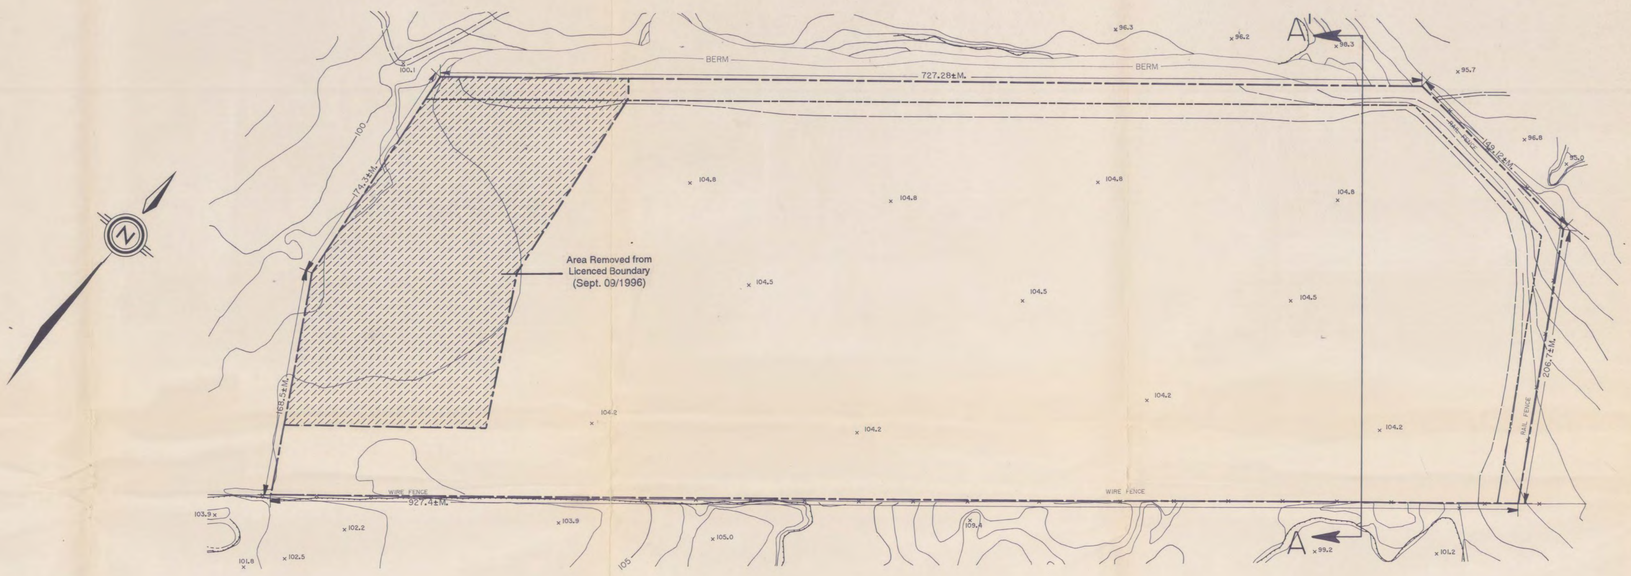
To allow Phases 1 & 2 to operate concurrently and simultaneous in various locations due to the differently quality of material throughout the site and also the high concentration of clay ridges.

PROGRESSIVE REHABILITATION AND FINAL REHABILITATION PLAN



HORIZONTAL SCALE - 2000

VERTICAL SCALE - 200



REHABILITATION

Maximum hectarage to be rehabilitated is approximately 22.3 hectares. Progressive rehabilitation will be carried out on the site. In the general this would be carried out by filling from a westerly to easterly direction.

The pit will be backfilled with acceptable inert material. The final site elevation will be approximately 104 metres, sloping slightly to the south, as indicated on the Rehabilitation Plan. The sloped surface will then be sewn with a grass legume mixture.

Adequate soil would be spread on the site to facilitate an adequate growth for grass legume mixture.

The site can then be adequately utilized for building development or pasture.

1 Introduction

A Servicing Brief is being prepared on behalf of Minto Communities Inc. (Minto) for a portion of its lands in Barrhaven South. The first phase of Minto's development (Phase 1) is located at 3872 Greenbank Road, north of Barnsdale Road.

1.1 Background

The subject site is part of the lands tributary to the Corrigan Stormwater Management (SWM) Facility, which was designed to service a drainage area of 145 ha. The storm servicing of the lands tributary to the Corrigan SWM Facility and the detailed design of the pond were carried out by IBI Group, presented in "Corrigan Stormwater Management Facility Stormwater Management Report and Design Brief," originally completed in 2008 and updated in 2010. The Corrigan SWM Facility is designed to control urban runoff for the 145 ha catchment area.

Minto's lands west of Greenbank Road were represented by Areas A1 and A2 in the Corrigan SWM Report and Design Brief. The drainage area plan from the report is enclosed in **Attachment A** for reference. In the Corrigan SWM Report and Design Brief, Area A1 represents rural lands, while Area A2 is designated for development. The minor system capture from A1 is the total flow, while from A2 is a combination of 85 l/s/ha for residential development and 20 l/s/ha for park area. The minor system flow is conveyed by the Greenbank Road trunk storm sewer to the Corrigan SWM Facility. The maximum release rate from A1 and A2 to the trunk storm sewer is 3 cms. With respect to major system flow, approximately 1.2 cms cascades overland to the downstream development to the north, tributary to the Todd SWM Facility.

Construction of the Corrigan SWM facility was completed in 2010.

1.2 Objective

IBI Group has been retained to provide stormwater management support and to update the previous study with respect to the Phase 1 development, taking into consideration updated City of Ottawa stormwater management guidelines presented in City of Ottawa Technical Bulletins ISDTB-2012-1 (January 31, 2012), ISDTB-2012-4 (June 20, 2012), and ISDTB-2014-1 (February 5, 2014).

1.3 Summary of Site Servicing Requirements

The following is a summary of the stormwater management site servicing requirements as established by the Corrigan SWM Servicing and Design Brief:

- The maximum minor system flow capture in the Greenbank trunk storm sewer from Areas A1 and A2 is 3 cms.
- The major flow cascading downstream from Areas A1 and A2 is 1.2 cms (0.9 cms at the western overflow location and 0.3 cms at the eastern overflow location).

2 Hydrological Evaluation

Preliminary modeling of the subject site has indicated that to meet the release flow rates summarized in Section 1.3, the surface ponding in the Phase 1 street sags is insufficient to achieve City of Ottawa guidelines. It is therefore proposed to retain the major flow in a dry facility. This provides an opportunity to eliminate the major system overflow from Phase 1, minimizing impact on the downstream lands.

The location of Phase 1 development in relation to the overall Corrigan SWM System is indicated on **Figure G-1**. It is proposed to build a temporary Phase 1 dry facility in the south-east corner of Phase 1.

The preliminary sizing of the Phase 1 dry facility was completed using SWMHYMO. This technique offers a single storm event flow generation and routing. It is also consistent with the hydrological evaluation completed for the overall Corrigan SWM System. Land use, storm events and input parameters are discussed in this section. A model schematic is presented on **Figure G-2** and model files are enclosed in **Attachment A**.

The hydrographs generated in the SWMHYMO model representative of the Phase 1 development were exported to the XPSWMM model of the Corrigan SWM System, discussed in **Section 3**.

2.1 Land Use and Drainage Areas

Phase 1 development measures 23.96 ha (interim pond inclusive) and is comprised of single family units, townhouses, park and a school. The majority of the Phase 1 development, 20.8 ha, contributes minor runoff to the Greenbank Road trunk storm sewer and major flow to the proposed Phase 1 dry facility. The remainder of the site, 2.2 ha, contributes total runoff directly to the Greenbank Road trunk storm sewer. The Greenbank Road trunk storm sewer conveys flow to the Corrigan SWM Facility.

In addition to the major flow from the 20.8 ha urban development, 22.6 ha of upstream rural lands contribute runoff to the Phase 1 dry facility.

The drainage area plan is presented on **Figure G-2**.

Table 2.1 Drainage areas

DRAINAGE AREA		OUTLET	AREA (HA)
PH1A	Phase 1 development	Minor flow to Greenbank Road trunk storm sewer; major flow to Phase 1 dry facility	20.8
PH1B	Phase 1 development	Total flow to Greenbank Road Trunk Storm Sewer	2.2
RURAL	Upstream rural area	Total flow to Phase 1 dry Facility	22.6

2.2 Storm Events and Input Parameters

The main hydrology parameters are summarized below and supporting calculations are provided in **Attachment A**.

- **Storm Events** The sizing of the Phase 1 dry facility was completed using the 100 year 24 hour SCS Type II storm event. This is consistent with the evaluation completed for the overall Corrigan SWM System.

- **Imperviousness** The imperviousness value for Phase 1 development is based on the runoff coefficient applied by JL Richards, who are completing the subdivision design. The runoff coefficient is a value applied to developments of similar land use.
- **Time to Peak** Time to peak for the upstream rural area was established using the Uplands Method, which accounts for elevation, distance and land use within the drainage area to estimate velocity of runoff. The time of concentration (Tc) is then calculated based on velocity, from which time to peak is determined applying the formula 0.6Tc (based on the SWMHYMO User's Manual). It is the time to peak (Tp) that is applied in the model. Supporting calculations are enclosed in **Attachment A**.
- **Infiltration** For Phase 1 development, infiltration losses were selected to be consistent with the City of Ottawa Sewer Design Guidelines (2004). The Horton values are as follows: f_o = 76.2 mm/h, f_c = 13.2 mm/h, k = 0.00115 s^{-1}. The SCS methodology was applied to the upstream rural area. A CN value of 77 was selected, consistent with the value applied in the evaluation of the overall Corrigan SWM System. It should be noted that evaluation of the overall Corrigan SWM System was completed applying the SCS methodology in the Corrigan SWM Report and Design Brief.
- **Length** The impervious length applied is based on an average measured length through the catchment and the calculated length based on the SWMHYMO User's Manual. The pervious length is based on average lot depth. This approach is consistent with the City of Ottawa Sewer Design Guidelines. Supporting calculations are enclosed in **Attachment A**.
- **Initial Abstraction (Depression Storage)** Depression storage depths of 0.8 mm and 1.5 mm were used for impervious and pervious areas, respectively. These values are more conservative than those in the City of Ottawa Sewer Design Guidelines.
- **Manning's Roughness** Manning's roughness coefficients of 0.013 and 0.25 were used for impervious and pervious areas, respectively.
- **Slope** A slope of 0.2% was used for impervious surfaces and a slope of 2% was used for pervious areas (lot grading).
- **Allowable Release Rates** As noted above, due to topographical constraints, runoff from approximately 2.2 ha of the Phase 1 development adjacent to Greenkbank Road will drain directly to the Greenbank Road trunk storm sewer. The allowable minor system release rate from the remaining Phase 1 development has been optimized based on the available capacity in the Greenbank Road trunk storm sewer less that used by the 2.2 ha and by the dry pond outflow. An outflow of 500 l/s is proposed for the pond. The allowable release rates have been coordinated with JL Richards.
- **On-site Storage** On-site storage was applied to the Phase 1 development as follows: 50 cu-m/ha was applied to the 2.2 ha portion of Phase 1 and 40 cu-m/ha was applied to the remaining Phase 1 development. The on-site storage has been coordinated with JL Richards.

The main hydrological parameters applied in the SWMHYMO model are summarized in the below table.

Table 2.2 Summary of input parameters

DRAINAGE AREA ID	AREA (HA)	IMP (%) [TIME TO PEAK (H)]	LENGTH, LGI (M)	MINOR SYSTEM CAPTURE (CMS)	SURFACE STORAGE
PH1A	20.8	65	424	2.290	40 cu-m/ha = 832 cu-m
PH1B	2.2	65	196	0.510	50 cu-m/ha = 110 cu-m
RURAL	22.6	[0.67]	N/A	N/A	N/A

3 Hydraulic Evaluation

The hydrographs generated in SWMHYMO representative of the Phase 1 development were downloaded to the overall XPSWMM model for hydraulic grade line (HGL) analysis of the existing Corrigan SWM System. The XPSWMM model schematic is enclosed in **Attachment A**. The hydraulic grade line analysis was evaluated using the 100 year SCS Type II storm event, consistent with the evaluation of the overall Corrigan SWM System.

During the 100 year event, the trunk storm sewer operates under free flow conditions, with the exception of the maintenance holes listed in the below table, at which surcharge occurs (refer to maintenance hole locations indicated on **Figure G-1**). At the locations where there are residential connections, the under-side of footing (USF) elevation is noted, and freeboard indicated. Otherwise, if there are no residential connections at the location of the maintenance hole, the USF elevation is indicated as not applicable (N/A), and only surcharge above the pipe obvert is indicated.

Table 3.1 Summary of HGL

MH	LOCATION	USF (M)	PIPE OBVERT (M)	HGL (M)	SURCHARGE (HGL – OBV) (M)	FREEBOARD (USF-HGL) (M)
119	Tucana Way	92.040	90.628	90.651	0.023	1.389
118	Tucana Way	92.250	90.765	90.848	0.083	1.402
117	Cambrian Road at Tucana Way	N/A	90.888	91.106	0.218	N/A
106A	Cambrian Road, west of Tucana Way	N/A	91.105	91.442	0.337	N/A
105B	Greenbank Road, south of Cambrian Road	N/A	91.615	91.834	0.219	N/A
104C	Greenbank Road	N/A	91.770	91.944	0.174	N/A
104B	Greenbank Road	92.375	91.863	92.056	0.193	0.319
104	Greenbank Road	92.500	91.914	92.104	0.190	0.396
106	Greenbank Road	N/A	92.070	92.274	0.204	N/A

MH	LOCATION	USF (M)	PIPE OBVERT (M)	HGL (M)	SURCHARGE (HGL – OBV) (M)	FREEBOARD (USF-HGL) (M)
110	Greenbank Road	N/A	92.240	92.454	0.214	N/A
103B	Greenbank Road	93.000	92.325	92.584	0.259	0.416
103	Greenbank Road	N/A	92.644	92.728	0.084	N/A

The 0.3 m minimum clearance between HGL and under-side of footing elevation is maintained along the existing trunk storm sewer tributary to the Corrigan SWM Facility. It is therefore concluded that the stormwater management concept proposed for the Phase 1 development does not negatively impact the performance of the overall system from a hydraulic grade line perspective.

4 Summary of the Conceptual Phase 1 Dry Facility

The conceptual dry facility profile is indicated on **Figure G-3**. It is proposed to provide the facility with a ditch inlet catch basin that will function as the outlet structure. The top of grate elevation will correspond to the lowest elevation of the pond at 97.0 m. Runoff will cascade through the top of grate and exit via an outlet pipe, which will be provided with an inlet control device to control the flow rate. The outlet pipe will tie in to the trunk storm sewer servicing Phase 1, proposed to extend from west to east along the southern Phase 1 property boundary. Orifice calculations to support the conceptual outlet structure design are enclosed in **Attachment A**. During 100 year conditions, the maximum storage used by the facility is 0.71 ha-m. The corresponding water level in the facility is 98.25 m, which has been shown on **Figure G-3**.

5 Conclusions and Recommendations

The first phase of Minto's Barrhaven South development (Phase 1) is located at 3872 Greenbank Road, north of Barnsdale Road.

The subject site is part of the lands tributary to the Corrigan Stormwater Management (SWM) Facility, which was designed to service a drainage area of 145 ha. The storm servicing of the lands tributary to the Corrigan SWM Facility and the detailed design of the pond were carried out by IBI Group, presented in "Corrigan Stormwater Management Facility Stormwater Management Report and Design Brief," originally completed in 2008 and updated in 2010. The Corrigan SWM Facility is designed to control urban runoff for the 145 ha catchment area. Construction of the Corrigan SWM facility was completed in 2010.

Minto's lands west of Greenbank Road were represented by Areas A1 and A2 in the Corrigan SWM Report and Design Brief. The drainage area plan from the report is enclosed in **Attachment A** for reference. In the Corrigan SWM Report and Design Brief, Area A1 represents rural lands, while Area A2 is designated for development. The minor system capture from A1 is the total flow, while from A2 is a combination of 85 l/s/ha for residential development and 20 l/s/ha for park area. Minor system flow is conveyed by the Greenbank Road trunk storm sewer to the Corrigan SWM Facility. The maximum release rate from A1 and A2 to the trunk storm sewer is 3 cms. With respect to major system flow, approximately 1.2 cms cascades overland to the downstream development to the north, tributary to the Todd SWM Facility.

The following is a summary of the stormwater management site servicing requirements as established by the Corrigan SWM Servicing and Design Brief:

- The maximum minor system flow capture in the Greenbank trunk storm sewer from Areas A1 and A2 is 3 cms.
- The major flow cascading downstream from Areas A1 and A2 is 1.2 cms (0.9 cms at the western overflow location and 0.3 cms at the eastern overflow location).

IBI Group has been retained to provide stormwater management support and to update the previous study with respect to the Phase 1 development, taking into consideration updated City of Ottawa stormwater management guidelines presented in City of Ottawa Technical Bulletins ISDTB-2012-1 (January 31, 2012), ISDTB-2012-4 (June 20, 2012), and ISDTB-2014-1 (February 5, 2014).

The Phase 1 development measures 23.96 ha (interim pond inclusive) and is comprised of single family units, townhouses, park and a school. The majority of the Phase 1 development, 20.8 ha, contributes minor runoff to the Greenbank Road trunk storm sewer and major flow to the proposed Phase 1 dry facility. The remainder of the site, 2.2 ha, contributes total runoff directly to the Greenbank Road trunk storm sewer. In addition to the major flow from the 20.8 ha urban development, 22.6 ha of upstream rural lands contribute runoff to the Phase 1 dry facility.

Preliminary modeling of the subject site has indicated that to meet the release flow rates summarized in Section 1.3, the surface ponding in the Phase 1 street sags is insufficient to achieve City of Ottawa guidelines. It is therefore proposed to retain major flow from the majority of Phase 1 in a dry facility. This provides an opportunity to eliminate the major system overflow from Phase 1, minimizing impact on the downstream lands.

The location of Phase 1 development in relation to the overall Corrigan SWM System is indicated on **Figure G-1**. It is proposed that the temporary Phase 1 dry facility be located in the south-east corner of Phase 1, abutting Greenbank Road to the west (refer to **Figure G-2**). The preliminary sizing of the Phase 1 dry facility was completed using SWMHYMO. This technique offers a single storm event flow generation and routing. It is also consistent with the hydrological evaluation completed for the overall Corrigan SWM System. A model schematic is presented on

Figure G-2 and model files are enclosed in **Attachment A**. The conceptual dry facility profile is indicated on **Figure G-3**.

The hydrographs generated in SWMHYMO representative of the Phase 1 development were downloaded to the overall XPSWMM model for hydraulic grade line (HGL) analysis of the existing Corrigan SWM System. The XPSWMM model schematic is enclosed in **Attachment A**. The hydraulic grade line analysis was evaluated using the 100 year SCS Type II storm event, consistent with the evaluation of the overall Corrigan SWM System.

The HGL elevations for those maintenance holes at which there is surcharge are presented in **Table 3.1**. If there are no residential connections at the location of the maintenance hole, the USF elevation is indicated as not applicable (N/A), and only surcharge above the pipe obvert is indicated. Otherwise, at the locations where there are residential connections, the under-side of footing (USF) elevation is noted, and freeboard indicated. The 0.3 m minimum clearance between HGL and under-side of footing elevation is maintained along the existing trunk storm sewer tributary to the Corrigan SWM Facility.

It is therefore concluded that the stormwater management concept proposed for the Phase 1 development does not negatively impact the performance of the overall system from a hydraulic grade line perspective and the Corrigan SWM System will perform as designed.

Time to Peak Calculations

The time of concentration (Tc) calculation is based on the Uplands Method, SCS National Engineering Handbook, 1972. The time to peak (Tp) calculation is based on the SWMHYMO User's Manual.

Equations:

$$T_c = \frac{L}{v} \times \frac{1}{3600} \quad \text{and} \quad T_p = 0.6 \times T_c$$

where:

T_c	time of concentration (h)
T_p	time to peak (h)
L	hydraulic length of watershed (m)
v	velocity from Uplands Method relationship between watershed slope and velocity (m/s)
0.6	constant to multiply time of concentration by to determine time to peak (as outlined in SWMHYMO manual)

Rural Area:

Section I
L = 450 m
Slope = (108.0 m – 102.0 m) / 450 m x 100 = 1.33 %
Corresponding velocity (overland flow: pasture), v ≈ 0.25 m/s
T_c = (450 m / 0.25 m/s) x (1 h / 3600 s) = 0.50 h

Section II
L = 220 m
Slope = (102.0 m – 101.0 m) / 220 m x 100 = 0.45 %
Corresponding velocity (overland flow: pasture), v ≈ 0.13 m/s
T_c = (220 m / 0.13 m/s) x (1 h / 3600 s) = 0.47 h

Section III
L = 180 m
Slope = (101.0 m – 97.0 m) / 180 m x 100 = 2.22 %
Corresponding velocity (overland flow: pasture), v ≈ 0.34 m/s
T_c = (180 m / 0.34 m/s) x (1 h / 3600 s) = 0.15 h

Tp = 0.6 (0.50+0.47+0.15) = 0.67 h

Length Parameter

Area ID	Area (ha)	Calculated Length (m)	Measured Length (m)	LGI (m)
PH1A	20.8	475	372	**424**
PH1B	2.2	270	121	**196**

Where calculated length is based on the formula:

L_c = ((Area) / 1.5)$^{0.5}$
where area is measured in sq-m

Orifice Calculation

Location	Water Level (m)	Centre of Orifice (m)	Approx. Head (m)	Area a x a (m)	Actual Flow Q_a (l/s)
Pond Outlet	98.25	96.375	1.875	**0.150**	81.9
	97.75	96.375	1.375	**0.150**	70.1
	97.25	96.375	0.875	**0.150**	55.9
	96.75	96.375	0.375	**0.150**	36.6

Mr. Guy Forget
Senior Water Resources Engineer
J.L. Richards & Associates Limited
864 Lady Ellen Place, Ottawa, ON K1Z 5M2

Dear Mr. Forget:

RESPOND TO THE CITY OF OTTAWA COMMENT - CORRIGAN SWM FACILITY

The purpose of this letter is to respond to the City of Ottawa comment:

"Please provide a table summarizing water quality volumes for the Corrigan SWM Facility. The Table should show updated drainage areas, imperviousness, permanent pool volume and extended detention storage volume. The areas and imperviousness values shown in Figure 2 of the July 2010 Corrigan SWM Facility Design Brief differ than what is shown in Appendix D1 of the JLR Submission. The table is required to confirm that the Corrigan SWM Facility will provide sufficient water quality volumes to achieve enhanced water quality treatment for Quinn's Pointe lands."

Subsequent to the submission the "Corrigan Stormwater Management Facility Stormwater Management Report and Design Brief" (July 2010), IBI Group completed a revision of the "Stormwater Management Barrhaven South" (October 2014). Revisions made to the drainage area as part of the most recent October 2014 Servicing Brief Report have been incorporated in this response to maintain consistency (see Table 1).

In addition, Figure A has been provided to present the most updated drainage area plan. Water quality volumes have been updated in Table 2 and have been compared to the July 2010 data. As outlined within the July 2010 report, the SWM facility provides 1.60 ha-m and 0.60 ha-m of permanent and extended storage, respectively, exceeding the water quality volume requirements. Supporting water quality volume calculations has been attached to these responses.

Sincerely yours,

IBI GROUP

Shagha Attar

Table 2: Water Quality Volumes

	Enhanced Level of Protection – Hybrid Wet Pond Overall Removal Efficiency of TSS 80%			
	Drainage Area (ha)	Imperviousness Ratio (Unit Storage for Hybrid Wet Pond) (%)	Permanent Storage (m^3)	Extended Detention Storage (m^3)
June 2015	147.5	47	14307	5900
July 2010 submission	145.0	49	14210	5800

The SWM facility provides 1.60 ha-m and 0.60 ha-m of permanent and extended storage, respectively, exceeding the water quality volume requirements.

Mr. Guy Forget –June 9, 2015

Water Quality Volumes Calculations

The Stormwater Management Facility is being designed as a hybrid wet pond at an Enhanced Level of Protection.

Drainage area = 147.5 ha

Total weighted imperviousness ratio = 47%

From MOE Stormwater Management Planning and Design Manual, March 2003. p. 3-10:

Protection Level	SWMP Type	**Storage Volume (m^3/ha) for Impervious Level**	
		35 %	**55 %**
Enhanced 80% long-term S.S. removal	Hybrid Wet Pond	110	150

Total storage volume for hybrid wet pond:

$$Y_2 = Y_1 + ((X_2 – X_1)/(X_3 – X_1)) \times (Y_3 – Y_1)$$

$$= 110 + ((47 – 35)/(55 – 35)) \times (150 – 110)$$

$$= 137 \text{ m}^3\text{/ha}$$

An imperviousness ratio of 47% corresponds to a total storage volume of 137 m^3/ha.

If extended detention = 40 m^3/ha
Then permanent storage = (137m^3/ha – 40 m^3/ha) = 97 m^3/ha

Therefore:
Permanent storage volume = 97 m^3/ha x 147.50 ha = 14307 m^3 = 1.43 ha-m
Extended detention volume = 40 m^3/ha x 147.50 ha = 5900 m^3 = 0.59 ha-m

RE: Barrhaven South Urban Expansion Area (BSUEA) – Potential Infiltration Measures

BACKGROUND

Based on regulatory requirements and the findings of the Geotechnical Engineer (Paterson), storm servicing for the BSUEA will need to be developed with infiltration measures to promote groundwater recharge in order to achieve a water balance and maintain the operation of the shallow overburden aquifer.

Infiltration measures are promoted in the MOECC 2003 Stormwater Management Planning and Design Manual (SWMPDM) as well as the Credit Valley Conservation 2010 Low Impact Development Stormwater Management Planning and Design Guide (LIDSWPDG). A summary of options from these two publications, with considerations for application in the BSUEA, is outlined below.

GENERAL CONSIDERATIONS

Defining pre-development site conditions is essential prior to screening of potential stormwater best management practices (BMP). All environmental features and functions, which need to be considered in accordance with provincial, municipal and conservation authority development regulations, should be identified. At this early stage, measures are being considered in order to maintain post- to pre-development levels of infiltration to the overburden aquifer within the BSUEA. For this site, consideration should be given to the following design factors:

Depth to high seasonal groundwater table or Bedrock

Where infiltration measures are being integrated as part of storm servicing, the distance between the Bedrock or the underlying water table to the invert of the infiltration measure should be greater than 1 metre to allow sufficient depth for infiltration. Water table elevations are being confirmed by the Geotechnical Engineer via their monitoring program. However, the final depths to the water table will depend on site grading.

Groundwater and Soil contamination

Most pollutants in urban runoff are generally retained within the infiltration material and soils and, therefore, have a low to moderate potential for causing contamination of the groundwater. The exceptions include chloride and sodium resulting from de-icing salts applied to roads and parking areas during winter. The chlorine and sodium are not well attenuated in soil and can easily travel to shallow overburden aquifer. Infiltration of de-icing salt constituents is also known to increase the mobility of certain heavy metals in soil (e.g., lead, copper and cadmium), thereby raising the potential for elevated concentrations in the shallow overburden aquifer. However, very few studies that have sampled groundwater below infiltration facilities or roadside ditches receiving de-icing salt laden runoff have found concentrations of heavy metals that exceed drinking water standards.

To minimize risk of groundwater contamination, it is recommended that stormwater infiltration practices not be implemented within areas experiencing high traffic where large amounts of de-icing salts are applied, nor from pollution hot spots (e.g., source areas where land uses or activities have the potential to generate highly contaminated runoff such as vehicle fuelling, servicing or demolition areas). The infiltration measures should be prioritized where runoff is from source areas that are comparatively less contaminated such as roofs, low traffic roads and parking areas. Sedimentation pre-treatment practices (e.g., oil and grit separators, grass swales or bio-retention) should ideally first be applied before infiltration of road or parking area runoff.

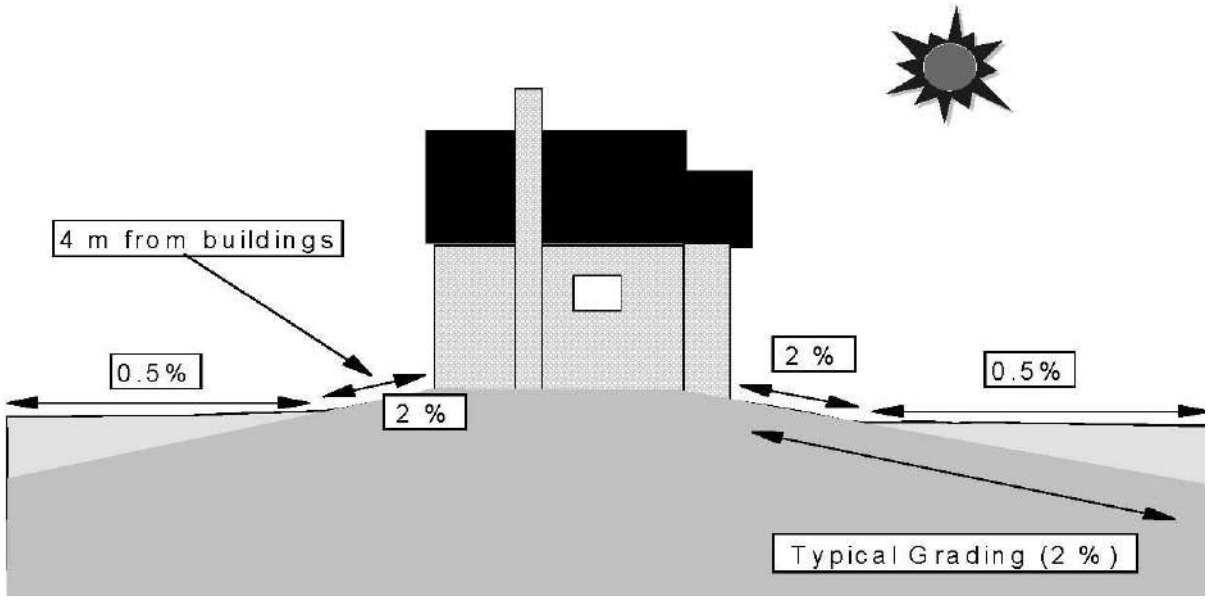
In terms of risk of soil contamination, the Credit Valley Conservation literature states that available evidence from monitoring studies indicates that small distributed stormwater infiltration practices do not contaminate underlying soils, even after 10 years of operation. Hence, at-source infiltration should be prioritized in the BSUEA.

SITE SPECIFIC LID MEASURES

Reduced Lot Grading

This method would promote infiltration as a result of using flat slopes along the grassed areas. This method can be contemplated when native soils exhibit percolation rates in excess of 15 mm/hr. If this percolation rate is exceeded, reduced lot grading down to 0.5% can be contemplated. Reduced slopes under post-development conditions would be used in the catchment parameters of the water balance modeling.

Figure 1: Schematic of Reduced Lot Grading (*MOECC 2003 SWMPDM*)



Key advantages of this infiltration method are:

- No additional servicing cost to the home builder;
- Reduced lot grading can be used along both front and rear yard grassed areas;
- Infiltration of rooftop runoff could also be promoted by the reduced slopes provided that eaves troughs are directed towards the grassed areas (rear and front);
- At-source infiltration; and
- No land loss by the home builder.

Key disadvantages of this infiltration method are:

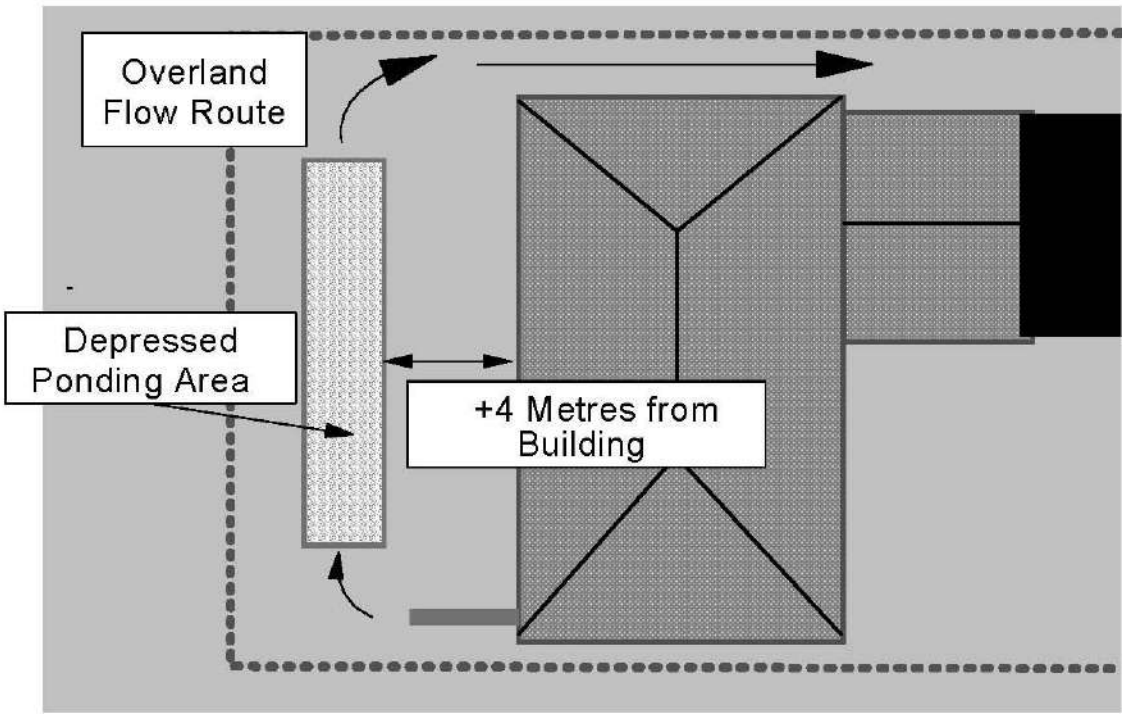
- Grading using 0.5% slope does not meet current design standards and would need to be further discussed with the City;
- Infiltration method could present some inconvenience to the property owner during larger precipitation events or during the spring freshet period when soils are partially frozen and less conducive to infiltration; and
- Reduced lot grading, although a low cost option, will not result in a significant increase in infiltration.

Operation and Maintenance: Since the measures would be located on private property, there would not be any operation and maintenance requirements for the City. However, property owners would need to be educated on the use and advantage of reduced lot grading and the requirement to continue to maintain a reduced grade along the grassed areas.

Roof Leader to Ponding Area

This method would promote infiltration by directing eaves troughs to a rear yard depressed area where the accumulated runoff would be infiltrated over a short period of time. This method can be contemplated when the native soils exhibit percolation rates in excess of 15 mm/hr.

Figure 2: Schematic of Roof Leader to Ponding Area (*MOECC 2003 SWMPDM*)



Key advantages of this infiltration method are:

- Minimum additional servicing cost to the home builder;
- Infiltration method could promote infiltration of runoff from both rooftop and grassed areas but would only be limited to the rear yard portion of the lot;
- At-source infiltration; and
- No land loss by the home builder.

Key disadvantages of this infiltration method are:

- Infiltration method could present some inconvenience to the property owner during larger precipitation events or during the spring freshet period when soils are still frozen and less conducive to infiltration;

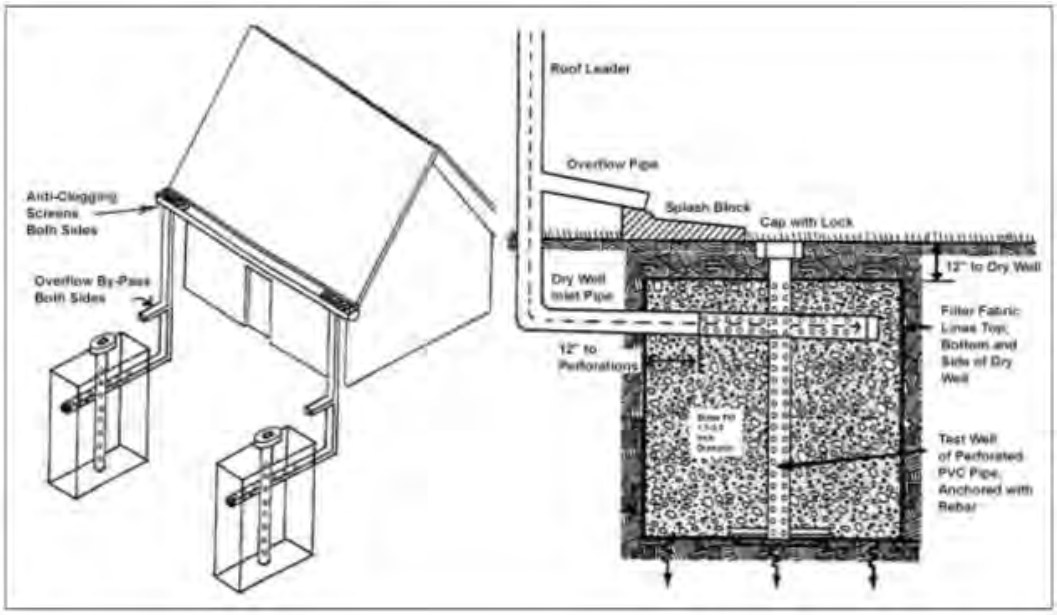
- Ponding area would be located on private property where the City would not have any control. Consequently, there will be a need to discuss with the City to ensure that the additional infiltration can be taken into consideration as part of the water balance analysis. Currently, rear yard storage cannot be accounted for in the modelling as per the Ottawa Sewer Design Guidelines.

Operation and Maintenance: Since the measures would be located on private property, there would not be any operation and maintenance requirements for the City. However, property owners would need to be educated on the use of the rear yard storage and continue to maintain the storage capacity following purchase of the lot. There should not be general maintenance requirements any greater than normal lawn maintenance particularly if the depressed area is designed with gentle slopes. However, the roof leaders will need to be kept directed away from impervious surfaces and the discharge area should be kept free of traffic so that the soil is not compacted.

Roof Leader to Soakaway Pit

This method would promote infiltration of the rooftop flows. This method can be contemplated when; i) the native soils exhibit percolation rates in excess of 15 mm/hr, and ii) when a minimum distance of 1 m can be observed between the bottom of the infiltration trench and the high seasonal groundwater table. Runoff reductions of up to 50% are estimated when used on HSG Class A and B soils, which are found over a large area of the BSUEA.

Figure 3: Schematic of a dry well soakaway (*Credit Valley Conservation 2010 LIDSWPDG*)



Key advantages of this infiltration method are:

- Infiltration method could promote infiltration originating from the rear rooftop area;
- Infiltration method is suited on deeper lots as the trench is to be located minimum 4 m away from the foundation;
- At source infiltration; and
- No land loss by the home builder.

Key disadvantages of this infiltration method are:

- Additional servicing cost to the home builder to construct onto the private property; i) the eaves troughs, and ii) the buried perforated pipe within the a trench;

- Infiltration method is not suited for small lots as the trench is to be located minimum 4 m away from the foundation;
- Soakaway pit would be located onto private property where the City would not have any control. Consequently, there will need to be some discussions with the City to ensure that the benefits of this method can be used as part of the water balance analysis.
- Only a relatively small drainage area would be serviced by this system.

Operation and Maintenance: Since the measures would be located on private property, there would not be any operation and maintenance requirements for the City. However, property owners would need to be educated on the use of the rear yard storage and continue to maintain the storage capacity following purchase of the lot.

Rear Yard Perforated Drainage System equipped with a Perched CB Outlet and Lead to the Front Yard
This method would promote infiltration of runoff originating from the rear portion of the lots. This method can be contemplated when the native soils exhibit percolation rates in excess of 15 mm/hr.

Key advantages of this infiltration method are:

- Runoff originating from both rooftop and grassed area (rear yard) could be infiltrated;
- Additional servicing cost to the home builder resulting from the additional sections of perforated pipe system and trench;
- At source infiltration; and
- No land loss by the home builder.

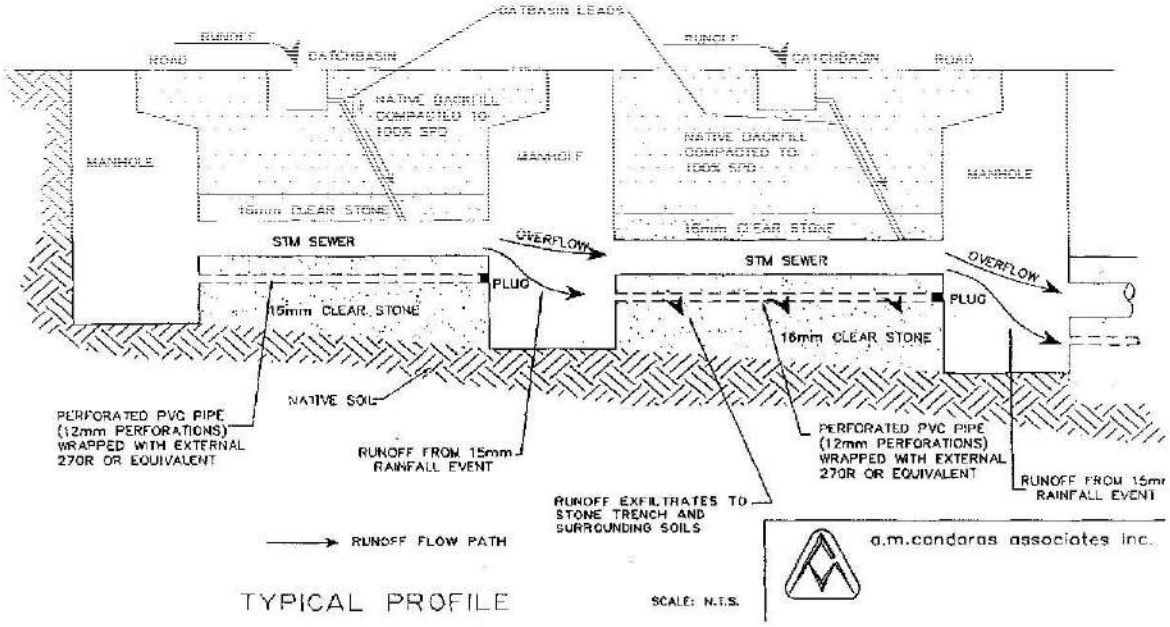
Key disadvantages of this infiltration method are:

- Infiltration method could present some inconvenience to the property owner due to ponding. This inconvenience could occur during larger precipitation events or during the spring freshet period when soils are partially frozen and less conducive to infiltration as ponding would occur at the perched CB; and
- Depressed area at the perched CB would be located at the back of the property where the City may have limited access though there could be easement arrangements set up. Consequently, there will need to be some discussions with the City to ensure that the benefits of this method can be used as part of the water balance analysis.

Operation and Maintenance: Regular inspection and cleaning out of the perched CB outlet would be required and property owners would need to be educated on the use of the system and to ensure operation is maintained following purchase of the lot.

Etobicoke Exfiltration System (ROW pervious pipe system)
This method would promote infiltration by intercepting runoff away from the main storm sewer system. This method can be contemplated when; i) the native soils exhibit percolation rates in excess of 15 mm/hr, and ii) when a minimum distance of 1 m can be observed between the invert of the perforated pipe and the high seasonal groundwater table.

Figure 4: Schematic of the City of Etobicoke Exfiltration System (*MOECC 2003 SWMPDM*)



Key advantages of this infiltration method are:

- infiltration method is carried out continuously along the ROW (i.e., not a single point) and relatively large areas can be treated;
- Perforated pipe systems have achieved runoff reductions of up to 95% in Ontario studies and are estimated to achieve runoff reductions of up to 85% in HSG Class A and B soils such as those found in the BSUEA.
- Modelling of this infiltration method for water balance would take advantage of the second pipe system and infiltration capabilities of the clear stone envelope and native material;
- infiltration system has proven its efficiency in Ontario; and
- infiltration method would result in no additional land loss by the developer.

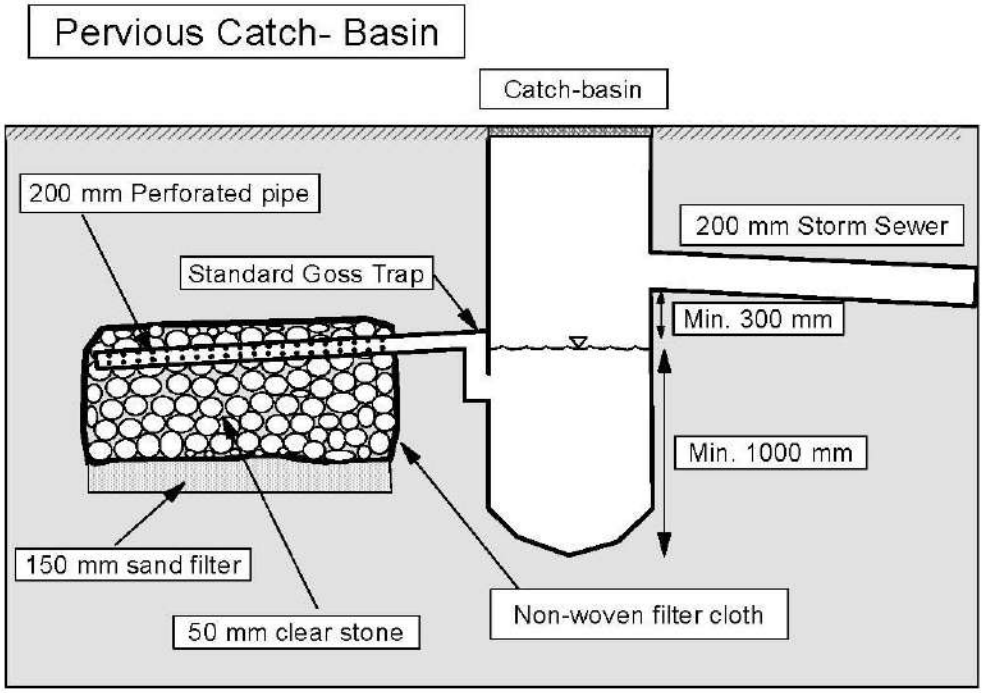
Key disadvantages of this infiltration method are:

- A greater servicing cost to the developer as a result of the construction of the perforated sewer system and the deeper excavation;
- Pre-treatment of the stormwater runoff is preferred, such as grass swales or leaf screens, to prevent clogging of the system; and
- Modelling of this infiltration method would easily be integrated in the water balance. However, the reduction in peak flows would likely not allow for a reduction in pipe of the main storm sewer system.

Operation and Maintenance: After its implementation, there would be a requirement for regular inspections to ensure that there is continual drainage function and drainage is completed within 72 hours following a storm event. If exfiltration to the shallow aquifer decreases over time, then pumping and cleaning with a high-pressure nozzle could be required or, alternatively, replacement of the filter media. Perforated pipe systems with grass swale pre-treatment have been observed to continue to function well up to 20 years following installation.

Pervious Catch Basins
Pervious catch basins are normal catch basins equipped with a larger sump or pre-treatment filters connected to an exfiltration storage medium. The exfiltration system could be an enlarged version of the roadway subdrains.

Figure 5: Schematic of Pervious Catchbasin (*MOECC 2003 SWMPDM*)



Key advantages of this infiltration method are:

- infiltration method is carried out continuously along the ROW (i.e., not a single point) and can effectively treat a relatively large area; and
- Incremental cost to the builder lies with the enlarged sumps or filters and the enlarged subdrain.

Key disadvantages of this infiltration method are:

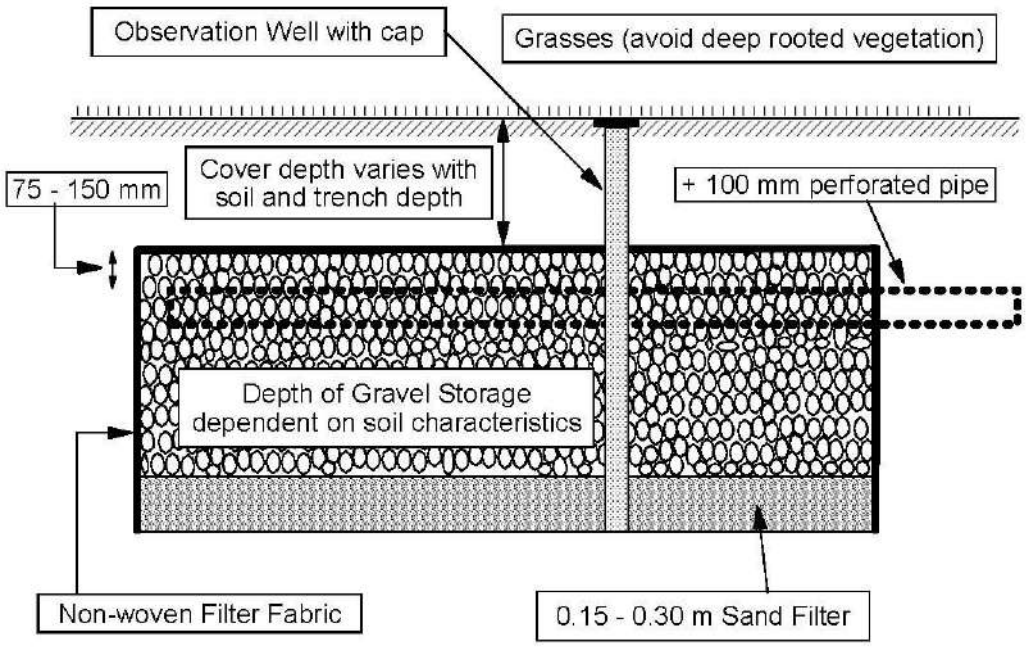
- Oversized sump or catch basin filters to provide TSS removal;
- Implementation of this method will require some discussions with the City (ROW group) to accept ownership of non-standard infrastructure (oversized sumps, enlarged subdrains, potential filters, etc.);
- Additional servicing cost to the developer as a result of the proposed non-standard infrastructure; and
- Discussions to be held with the City to ensure that the additional infiltration can be taken into consideration as part of the water balance analysis.

Operation and Maintenance: Catchbasins will need to be cleaned out on a regular basis to ensure effective operation. Inspections should be carried out to ensure that there is adequate exfiltration to the overburden (up to 72 hours to drain storms) after significant rainfall events. If there is a lack of drainage, then the filter medium may need to be replaced.

Infiltration Gallery
An infiltration gallery is a sub-surface collection system used to encourage and accelerate the process of groundwater recharge by allowing the captured runoff to infiltrate over time. This end-of-pipe facility would receive storm flows, which would be diverted from the conventional storm sewer system; pre-treatment is

highly recommended immediately upstream of the infiltration gallery to minimize clogging of medium. Infiltration systems can also include proprietary manufactured modular structures, which can be installed underground and have large void spaced and open bottoms to allow infiltration. These systems can be installed under car parks or in trench configurations. Runoff is expected to be reduced by around 85% based on previous testing in similar climates.

Figure 6: Subsurface Infiltration Trench (*MOECC 2003 SWMPDM*)



Key advantages of this infiltration method are:

- Modelling of this infiltration method for water balance would take advantage of the volume and infiltration of the native material.

Key disadvantages of this infiltration method are:

- Point source infiltration method unless trenches are set up over lengths or under a car park;
- Additional maintenance required by the City to prevent clogging by using pressure nozzle;
- Measures should be undertaken to reduce risk of soil or groundwater contamination;
- Additional servicing cost by the developer for the perforated pipes, manifold, geotextile, granular bedding, pre-treatment units, etc.; and
- Potential land loss by the home builder unless on park land or under car park areas.

Operation and Maintenance: Regular inspection is required to ensure continuity of function and that water drains away within 72 hours following a precipitation event. Replacement of the drainage medium may be required if a noticeable reduction in drainage time is observed. Infiltration trenches have been observed as continuing to function up to 30 years after installation.

Bio-retention

Bio-rentention or rain gardens are popular methods to promote overburden recharge. These infiltration practices are often easy to integrate into landscaped areas. This infiltration measure consists of a filter bed, which is a mixture of sand, fines and organic material under a mulch ground cover and plants adapted to stormwater practice. In cases where the rain garden does not have an underdrain and relies purely on

infiltration, then runoff reductions of up to 85% are estimated. However the use of an underdrain may be required depending on the soil characteristics.

Bio-retention is used in the Old Ottawa South area as part of the road landscape.

Figure 7: Bio-retention in Ottawa

Key advantages of this infiltration method are:

- Can be integrated into the landscaping features of the development
- Would achieve high levels of infiltration and the plant material would reduce soil and groundwater contamination risks.

Key disadvantages of this infiltration method are:

- Point source infiltration method unless used at each catch basin;
- Additional construction and maintenance costs; and
- Small potential land loss by the builder.

Operation and Maintenance: Regular inspection is required to ensure continuity of function and that water drains away within 72 hours following a precipitation event. Replacement of the drainage medium may be required if slow drainage exists. Rain gardens will require a similar level of maintenance as normal landscaped areas however landscape maintenance personnel may require additional training on the specific requirements for a rain garden or bio-retention cell.

Permeable Pavement

Permeable pavements are an alternate solution over traditional pavements as they allow stormwater to drain through them and infiltrate into the shallow overburden aquifer. Permeable pavement can be used in low trafficked roads, parking lots, driveways and pedestrianized walkways. They can be formed from interlocking pavers, grid pavers, pervious concrete or porous asphalt. Reductions in runoff of up to 85% without an underdrain are estimated based on previous studies. The use of an underdrain is dependent on the capacity of the underlying soils and may not be required above the esker.

Key advantages of this infiltration method are:

- Does not take up additional space to accommodate this infiltration measure.

Key disadvantages of this infiltration method are:

- If installed on private property, then education/awareness would need to be carried out to ensure the system is properly maintained;
- Risk of contamination from road salts. However, since the surface is free draining there is reduced need for road salts; and,
- Some specific maintenance measures are required depending on the type of permeable pavement used.

Operation and Maintenance: Regular inspection and twice annual surface sweeping is generally recommended. High pressure wash systems should not be used to prevent material being pushed further into the permeable membrane and blocking the system. Replacement of media is expected every 15-20 years.

CONCLUSION

A combination of techniques will be required within the BSUEA to promote recharge of the overburden aquifer to achieve a water balance. Some techniques will require acceptance from the City as well as commercial and institutional interests. A combination of techniques in a treatment train approach is preferred in order to reduce risks associated with contamination of groundwater from surface pollutants. The following measures when combined together would promote recharge of the overburden aquifer:

- Perforated pipe systems
- Bio-retention
- Permeable pavers
- Infiltration Galleries
- Roof Leaders to ponding areas / soakaway pits
- Permeable pavements in low trafficked areas or car parks (cul-de-sacs and the park and ride facility would be ideal areas for permeable pavements)

Other options which could be considered include:

- Reduced lot grading
- Pervious catchbasins

RE: BSUEA Modelling of EES Infiltration

BACKGROUND

The Barrhaven South Urban Expansion Area (BSUEA) consists of an area of 121 ha located immediately west of the current City of Ottawa Urban Boundary with Barnsdale Road along the southern limit. To support the BSUEA, a series of comprehensive documents will be prepared including a Master Servicing Study (MSS), which will outline water, sanitary and stormwater management servicing strategies. The subject lands, consisting of soils of moderate to high hydraulic conductivity, have been identified by the hydrogeotechnical engineer as one of the source of recharge of the Kars esker and underlying bedrock aquifers. As a result, one of the objectives of the Existing Condition Report (JLR, February, 2017) recommends that the post-development infiltration levels be maintained to pre-infiltration levels. Given the types of soils present within the subject lands that are conducive to infiltration, appropriate practices will be implemented to maximize the rate of infiltration and maintain pre-development infiltration levels.

A Technical Memorandum (JLR, September 2016) was issued to the City of Ottawa (City), which outlined potential Best Management Practices (BMPs) to increase infiltration within the BSUEA. During a follow-up meeting on September 7, 2016, discussions with the City identified a preference to infiltration measures that are located outside of private residential property and are, therefore, able to be maintained by the City. Measures proposed on institutional or commercial lands would be subject to maintenance requirements by owner. The Etobicoke Exfiltration System (EES) is a measure which can increase infiltration while being located within the ROW corridor thereby satisfying the City requirements with respect to maintenance along municipal right-of-way's (ROW). Therefore, the purpose of this Memorandum is to set out a post development test model and demonstrate how the EES and other non-structural BMPs can be used to maintain pre-development infiltration levels.

POST DEVELOPMENT DESIGN PARAMETERS

The Existing Conditions Report for the BSUEA (JLR, February, 2017) outlined the modeling methodology undertaken for the existing condition water budget assessment, which was performed using the PCSWMM platform. The infiltration rates used in the PCSWMM model were set based on saturated field hydraulic conductivities measured by the hydrogeotechnical engineer as part of their field investigation program. Based on the measured saturated field hydraulic conductivities, infiltration rates set in the existing condition model were found to vary between 49.8 mm/hr and 106.8 mm/hr. These infiltration rates were calculated from the saturated filed hydraulic conductivities in accordance with the Ontario Ministry of Municipal Affairs and Housing (MMAH) Building Code Supplementary Standard SB-6 (2012). The medium of each of the ranges, 49.9 mm/hr to 71.1 mm/hr, were used in the Existing Conditions modeling following a sensitivity analysis.

Best practices dictate that the infiltration rate used to assess the performance of infiltration measures must incorporate a safety factor that compensates for potential reductions in soil permeability due to a number of

factors such as compaction or smearing during construction, gradual accumulation of fine sediments over the lifespan of the infiltration measure and uncertainty over measured values. Based on the approach found in Appendix C of the Low Impact Development Stormwater Management Planning and Design Guide (Credit Valley Conservation Authority 2002), the recommended safety factor of 2.5 was used in the analysis. As a result, the post-development condition is simulated under infiltration rates in the range of 20 mm/hr (49.9 mm/hr / 2.5) to 28.4 mm/hr (71.1 mm/hr / 2.5).

Under the post-development conditions, three (3) types of residential development were considered with different levels of impervious land cover for each type (Table 1). The percent impervious is based on analysis of similar developments, mainly for the adjacent Quinn's Pointe development. The configuration of land cover is based on a conceptual layout of the development (See Figure 1, attached); however, there may be changes in the overall configuration during the remaining planning process.

The post-development condition model uses the same aquifers and groundwater parameters as the existing condition model. The same climate conditions are used as per the existing condition with the exception of the snow pack parameters, which are altered to reflect plowing potential across the impervious area as well as the potential for some snow may be removed from the catchment during the winter. This is a conservative assumption under post-development as it reduces the potential for infiltration during the snowmelt period.

Table 1: Land Use Impervious Values

Land Use Type	Area in Concept Plan	Percent Impervious
Single Family Units	23.3 ha	54%
Family Townhouses	6.4 ha	60%
Back to Back Units	2.3 ha	70%
Rear Lane Townhouses	1.1 ha	70%
Residential Weighted Average		56.8%
Local Roads	18.0 ha	70%
Collector Roads	6.5 ha	90%
Rear Lanes	0.3 ha	90%
ROW Weighted Average		75.5%

POST DEVELOPMENT CONDITION (WITHOUT ANY MEASURES) RESULTS

The PCSWMM model was updated to reflect the future condition parameters and was used in a continuous simulation mode. As envisioned, the model showed a reduction in the volume of infiltration due to the increased imperviousness as summarized in Table 2 below.

Table 2: Post Development Condition Water Budget Results

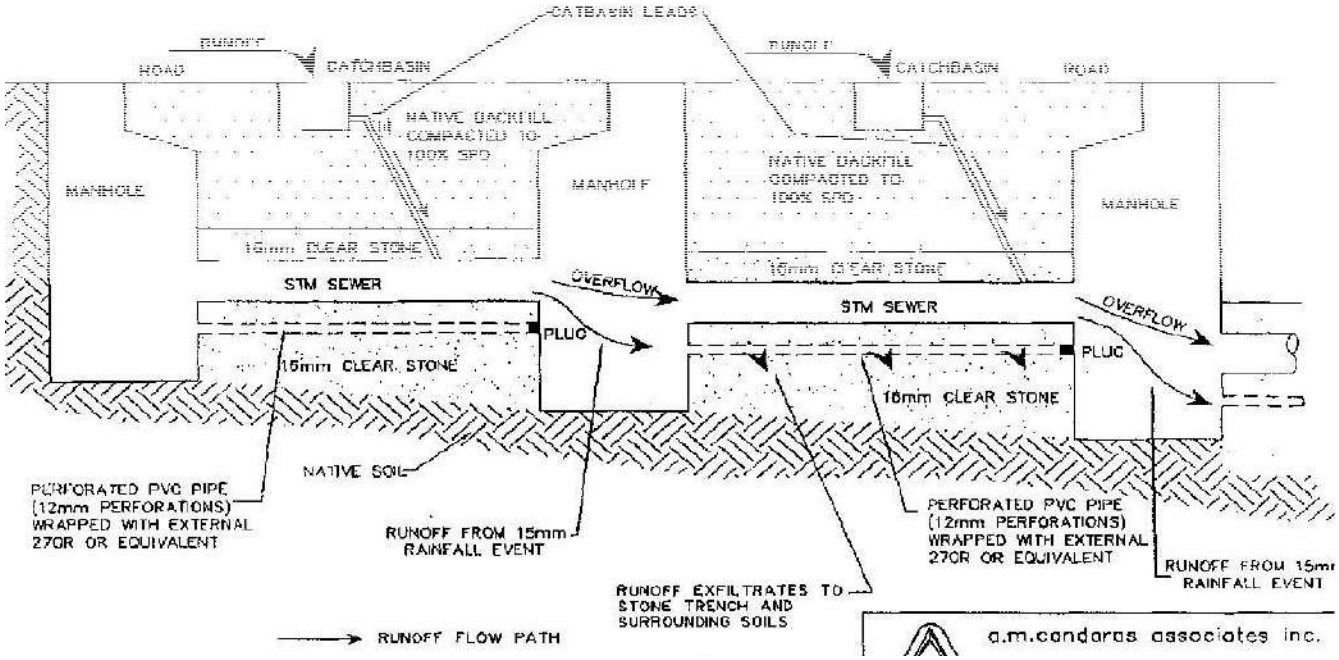
Annual Water Budget Components	Pre-development Annual Average Depth		Post Development Average Annual Depth	
Precipitation	844 mm	100%	844 mm	100%
Evapotranspiration	506 mm	60%	218 mm	26%
Infiltration	337 mm	40%	122 mm	14%
Surface Runoff	1 mm	0%	513 mm	61%

The above simulation results show a decrease in annual infiltration from 40% under pre-development conditions to 14% under post-development conditions. Hence, measures to re-infiltrate are required such that the objective of maintaining pre-development infiltration levels (40%) is achieved.

ETOBICOKE EXFILTRATION SYSTEM (EES)

The Etobicoke Exfiltration System (EES) (Figure 2) was developed, designed and constructed in the former City of Etobicoke (now part of the City of Toronto) in 1993. Its main objective was to restore the natural hydrologic cycle in an existing developed area. The EES consists of two perforated pipe sub drains constructed below the conventional storm sewer that is surrounded by a clear stone media, which collects and detains surplus stormwater runoff before reaching the conventional storm sewer line. The downstream ends of the perforated pipes are capped. The EES is intended to capture frequent storm events and the initial "first flush" of large storm events by trapping flow in the perforated pipe sub drain and surrounding media and infiltrate into the surrounding soils while larger events will overtop the capacity of the EES system and would then overflow to the conventional storm sewer system above as depicted on Figure 2.

Figure 2: Schematic of the City of Etobicoke Exfiltration System (*MOECC 2003 SWMPDM*)



EES MODELING APPROACH

With the modelling methodology used to assess the water budget under existing condition, and the water budget under post-development condition as detailed above, it is not possible to assess the impact from EES using the same modules; the above methodology uses only the Runoff module in SWMM and the EES has to be modelled as a hydraulic component. At this stage, a typical portion of the conceptual development has been extracted as a test area, with the addition of a conceptual stormwater sewer system and inclusion of the EES.

The test area consists of 8 subcatchments representing approximately 2 ha of residential development and 4 subcatchments representing approximately 460 m of ROW (see Figure 3 attached). The imperviousness of the residential catchments is the average of the residential land cover across the development as per Table 1

above and the ROW was set as having an imperviousness of 75.5% (based on the average of the different ROWs across the development). The width parameter will reflect the catchment flow lengths; however, all other parameters will remain as per the water balance modeling for the future condition above. Three (3) infiltration values will be utilised for the Horton Coefficient Parameters based on the infiltration values used in the full post development model above: a value at the maximum end of the range (28.44 mm/hr), a value at the lower end of the range (20.3 mm/hr) and the weighted average value of 26.7 mm/hr; these rates have been reduced by a safety factor of 2.5 as previously described above.

For testing purposes, it will be assumed that the depth of the EES's granular envelope will be 950 mm that will include two 200 mm sub drains running along it. The void ratio of the clear stone is assumed at 40%, which is consistent with the document entitled "Planning and Design Manual of the Etobicoke Exfiltration System for Stormwater Management, John Tran and James Li, Ryerson University". The width of the granular envelope is related to the sewer trench width and will be 2.4 m for the testing purposes.

The EES is simulated by use of storage nodes at the upstream of each storm sewer section in the PCSWMM model. The storage node has a base area equal to the void space (40%) bottom surface area of the EES system (0.4 x 2.4 m wide x pipe length = 0.96 m x pipe length) and the depth of the EES is the depth of the unit plus additional depth to account for the additional volume in the sub-drains. Three (3) seepage parameters are simulated for sensitivity analysis as per the maximum, minimum and average infiltration values used in the Horton Coefficient parameters for the test area.

STORM EVENT ANALYSIS

The continuous simulation undertaken for the Existing Conditions water budget assessment was analysed to rank the precipitation events and determine the percentile of storm events. The 95th percentile was identified and used as the design target of the system based on the recommendation of the document entitled "Planning and Design Manual of the Etobicoke Exfiltration System for Stormwater Management, John Tran and James Li, Ryerson University". Based on this requirement, a storm capture of 22 mm in total rainfall depth was found to be the 95th percentile based on historical meteorological data (Figure 4); those 22 mm storm events ranged from short storm duration storms to longer durations that often exceeding 8 hours.

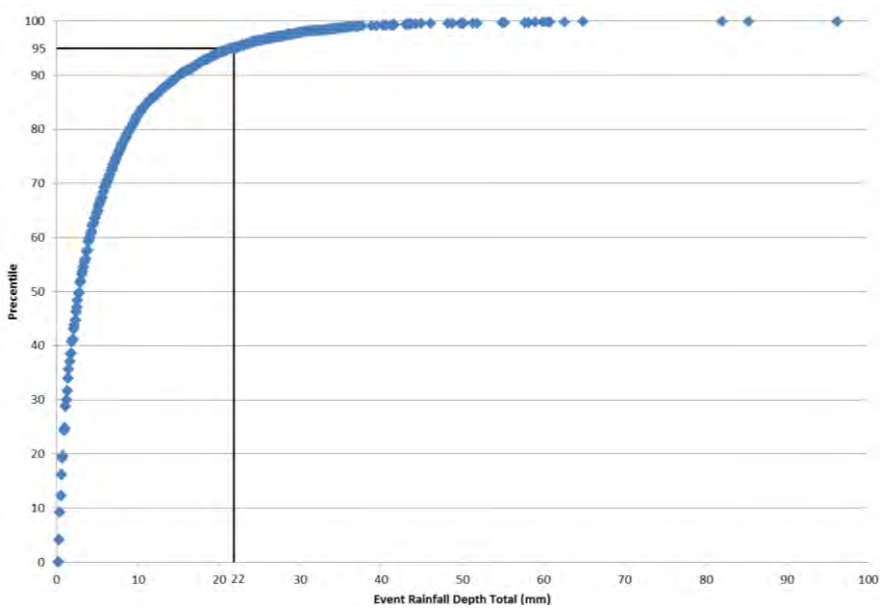


Figure 4: Rainfall Event Analysis

Based on the above statistical analysis, the proposed EES should be sized to accommodate storms of up to this depth without conventional storm flow occurring. Two (2) different storms were used as part of the performance evaluation of the EES; i) the 22 mm - 4 hour design storm (representing the 95th percentile), and ii) the standard 25 mm - 4 hour storm. The 4 hour duration is a conservative duration as those events have occurred over 5 hours to 40 hours during the 30 years of continuous data. Both storms are simulated as well as the continuous simulation of 30 years of precipitation data.

EES MODEL VERIFICATION

To verify that the test model is a true representation of the water balance of the area, the test model will be run under continuous simulation storm without the EES to determine if the performance of the test area has a similar future condition water balance as the study area as a whole. It should be noted that the overall model includes the two (2) existing aggregate extraction areas, which was not accounted for in the calculation of the weighted average for the land cover imperviousness or the weighted average of the infiltration value. Given that both aggregate extraction areas have licenses to continue their operations, full urbanization of these areas will not occur for some time. As a result, the performance of the EES excludes these areas. Additionally, the testing has not included any Institutional-Commercial-Industrial (ICI) land uses as it is envisioned that these areas will have an additional on-site infiltration target to achieve such that the proposed EES can be maintained along any types of land use without overloading the system. The targets for the ICI areas are described below in the "ICI Areas" section.

Given these differences between the study area as a whole and the test area, it is expected that the infiltration in the test area will be slightly higher and runoff slightly lower, which is shown in the results (Table 3).

Table 3: Post Development and Test Model Comparison

Annual Water Budget Components	Post Development Average Annual Depth		Test Model Continuous Simulation Average Annual Depth	
Precipitation	844 mm	100%	844 mm	100%
Evapotranspiration	218 mm	26%	251 mm	30%
Infiltration	122 mm	14%	161 mm	19%
Surface Runoff	513 mm	61%	417 mm	49%

Based on the above simulation results, it can be concluded that the test area is a suitable representation of the simulation of a residential area within the BSUEA. As a result, the test model is a suitable means to evaluate the performance of the EES and will be carried forward in the subsequent evaluations.

EES MODEL RESULTS

The target infiltration objective is to maintain the pre-development infiltration rate of approximately 40% under the post-development condition. The results summarized in the tables below show that the infiltration target is achieved in each of the infiltration scenarios and under both storm events as well as under the continuous simulation. It should be noted in the summary tables below, that the total infiltration is split between the catchment infiltration through the surface soils and the infiltration resulting from EES exfiltration; both of these components are added to obtain the total infiltration into the ground and aquifers.

Table 4: Performance Evaluation of EES: Continuous Simulation

Annual Water Budget Components	20.3 mm/hr Infiltration (Minimum)		26.7 mm/hr Infiltration (Weighted Average)		28.4 mm/hr Infiltration (Maximum)	
Precipitation	844 mm	100%	844 mm	100%	844 mm	100%
Evapotranspiration	251 mm	30%	251 mm	30%	251 mm	30%
Catchment Infiltration	159 mm	19%	161 mm	19%	162 mm	19%

Annual Water Budget Components	20.3 mm/hr Infiltration (Minimum)		26.7 mm/hr Infiltration (Weighted Average)		28.4 mm/hr Infiltration (Maximum)	
EES Exfiltration	387 mm	46%	386 mm	46%	386 mm	46%
Total Infiltration	546 mm	65%	547 mm	65%	548 mm	65%
Surface Runoff	32 mm	4%	31 mm	4%	31 mm	4%

Table 5: Performance Evaluation of EES: 22 mm - 4 hour Design Storm

Annual Water Budget Components	20.3 mm/hr Infiltration (Minimum)		26.7 mm/hr Infiltration (Weighted Average)		28.4 mm/hr Infiltration (Maximum)	
Precipitation	22 mm	100%	22 mm	100%	22 mm	100%
Evapotranspiration	0 mm	0%	0 mm	0%	0 mm	0%
Catchment Infiltration	7 mm	30%	7 mm	32%	7 mm	33%
EES Exfiltration	14 mm	65%	14 mm	64%	14 mm	62%
Total Infiltration	21 mm	95%	21 mm	96%	21 mm	95%
Surface Runoff	0.1 mm	0%	0 mm	0%	0.2 mm	1%

Table 6: Performance Evaluation of EES: 25 mm - 4 hour Design Storm

Annual Water Budget Components	20.3 mm/hr Infiltration (Minimum)		26.7 mm/hr Infiltration (Weighted Average)		28.4 mm/hr Infiltration (Maximum)	
Precipitation	25 mm	100%	25 mm	100%	25 mm	100%
Evapotranspiration	0 mm	0%	0 mm	0%	0 mm	0%
Catchment Infiltration	7 mm	27%	7 mm	29%	7 mm	30%
EES Exfiltration	15 mm	62%	15 mm	62%	15 mm	62%
Total Infiltration	22 mm	89%	23 mm	91%	23 mm	91%
Surface Runoff	2 mm	7%	1 mm	6%	1 mm	5%

The above simulation results show the following:

- Under the 95th percentile design storm (22 mm – 4 hour design event), there is marginal runoff occurring, which ranges between 0% and 1% of the annual precipitation depending on the simulated infiltration rate;

- Under the 95th percentile design storm (22 mm - 4 hour design event), the simulation results show that the greatest runoff occurred under the maximum infiltration rate scenario (28.4 mm/hr). The increase in surface runoff under the maximum infiltration scenario is due to more infiltration occurring along the surface in pervious areas that in turn will reduce the total flow entering the EES, which reduces the

wetted perimeter of storage in the EES. The latter is then used to calculate the exfiltration in the model and, therefore, the overall infiltration is reduced slightly.

- The overall impact of the varying infiltration values is found to be negligible across both design storms and the continuous simulation with only up to one (1) to two (2) millimetres difference in overall infiltration depth. Hence, setting the PCSWMM model with a constant infiltration rate of 26.7 mm/hr across the BSUEA would be a fair representation of the infiltration over the subject lands.

WATER QUALITY CONTROL

Table 3.2 of the MOECC of the publication entitled "Stormwater Management Planning and Design Manual, March 2003" sets the storage volume requirements for infiltration measures to achieve 80% TSS removal. Based on the average imperviousness used in the test model (i.e., 56.8% for the average residential area and 75.5% for the ROW), the required volume of water quality storage for the EES is 32 m³/ha. The storage volume increases to 42 m³/ha for areas with a 90% imperviousness level. Based on the sizing approach of the EES (95th percentile), the storage volume in the test model is on average 150 m³/ha. The proposed EES system, therefore, satisfies the requirements for water quality control in accordance with the MOECC for any of the proposed land uses. Any downstream end-of-pipe facility would then not be required to provide further water quality controls. On this basis, end-of-pipe facilities should be designed as dry detention facilities as the frequency of inflows will be limited to events likely exceeding 22 mm.

ICI AREAS

The test model was carried out in a residential area; however the runoff from ICI areas will contribute to the EES system through overland flow and captured by the conventional storm system. In order to maintain the same EES across the BSUEA, additional on-site controls will be needed as part of the servicing for any ICI developments to ensure that the EES is not overloaded and that its performance is not impacted under the 22 mm event as the results summarized above shows virtually no runoff during this storm event

Under a 22 mm storm event across a hectare of residential land (with an average percent impervious of 56.8%), 125 m³ of stormwater is captured and infiltrated with no runoff. Across a hectare of commercial area (with an average percent impervious of 90%), the same 125 m³ volume of stormwater is produced by 14 mm of rainfall. In order to maintain the same hydraulic loading to the EES to what is generated by residential areas, the commercial area would have to infiltrate on-site the difference between 14 mm and 22 mm. Hence, storm servicing for commercial blocks should be developed to infiltrate on-site the first 10 mm of surface runoff to maintain the same hydraulic loading and meet the performance objective of the EES. Similarly, for a hectare of institutional block with an assumed 70% imperviousness, the same 125 m³ volume of surface runoff is produced by 18 mm of rainfall. In order to maintain the hydraulic loading to the EES to the same than what is generated by residential areas, the institutional block would have to infiltrate the difference between 18 mm and 22 mm. Hence, storm servicing for institutional blocks should be developed to infiltrate the first 5 mm of surface runoff to maintain the same hydraulic loading and meet the performance objective of the EES.

In addition, servicing of the ICI areas would need to be developed to adhere to the Ottawa Sewer Design Guidelines where flows in excess of the storm sewer capacity must be detained on-site.

EES APPLICATION

Within urbanized areas, storm sewers will vary in size based on the extent of the serviced area. As a result, the trench for the storm sewer will also vary in width and will be designed in accordance to City standards. In addition, the proposed EES will need to be integrated into variable ROW corridor widths and be shared with other services including watermains and sanitary sewers and their associated service connections. To

accommodate the other services and reflect the different sewer sizes, the EES configuration and dimensions will need to be flexible to the various servicing constraints; however the design of the EES will require to maintain a volume per linear metre as per that modelled to ensure that the infiltration targets are met. To reflect the location of the storm sewer and EES within the ROW corridor, the service connections may have to be located either above or below the EES depending on the size of the storm sewers, its depth as well as the configuration of the sanitary sewers. Figures 5a – 5d (attached) show typical configurations along local and collector roads for both a 525 mm diameter and 1050 mm diameter storm sewers. At detailed design, the configuration of the EES will need to be adapted based on the local design constraints of each section of roadway

CONCLUSIONS AND RECOMMENDATIONS

The modeling demonstrates that the EES can be simulated with the hydraulic component of EPA SWMM and that when modelled, the EES can increase the post-development infiltration levels to above levels experienced under the pre-development condition, notwithstanding applying the recommended safety factor of 2.5 to the existing infiltration rates set based on the measured saturated hydraulic conductivities

Based on the conclusions above, the following recommendations are made:

- The EES is used to provide infiltration and water quality control as per the MOECC SWMPD for the residential and ROW runoff from the development with a Factor of Safety on the infiltration rates of 2.5.

- Storm servicing for any of the ICI areas be developed to achieve set target infiltration depths (on-site) of 10 mm and 5 mm for commercial and institutional areas, respectively in order to maintain the hydraulic loading to the EES the same to what is generated by residential development areas.

- Since the EES system can be modelled in PCSWMM, along with the hydraulic analysis of the storm sewer network and storage simulation, there is opportunity to be able to include the impact of such a system in the sewer and downstream dry pond facility design. By doing so, the benefits of the EES would be reflected in the end-of-pipe facility sizing.

- At the MSS stage, special attention should be devoted to areas having a high water table to determine whether an EES can be implemented within those areas as there must be a 1 m separation between the groundwater table and the bottom of the EES. When such areas are identified during the MSS, they will be accounted for in the analysis to confirm that the pre-infiltration levels have been achieved for all of the BSUEA, excluding the two (2) aggregate extraction areas. For such areas, alternate quality control measures will be investigated such as the provision of water quality units.

- Upon the acceptance in principle of the EES by regulatory agencies, recommendations from the geotechnical engineer will be sought to ensure that the structural integrity of the traditional storm sewer system is not impacted by the EES.

Re: BSUEA – EES Modelling – Site Wide Application
Infiltration Rates

Date: June 16, 2017

Job No.: 26610

CC: Hugo Lalonde, MCIP, RPP
Land Development Manager
Minto Communities - Canada

Purpose of Undertaking

This Memorandum was prepared to assess infiltration within the Barrhaven South Urban Expansion Area (BSUEA) given that the Etobicoke Exfiltration System (EES) would only be implemented along local roads due to the potential adverse impact of roadway salts along collectors and arterials.

Background

The review of background data as part of the hydrologeological Existing Condition Report (Paterson Group) revealed that the permeable overburden in the BSUEA was acting as a recharge area for the esker and bedrock aquifers located in the underlain soils within the BSUEA. As a result, a number of recommendations were drawn to minimize the impact to the esker. These recommendations included; i) the preservation of the pre-infiltration levels, ii) incorporating infiltration measures as part of the Subdivision's servicing to maintain pre-infiltration levels, and iii) distributed infiltration of "clean runoff". As part of Existing Condition Report completed by J.L. Richards & Associates Limited (JLR), a water budget analysis was carried out to ascertain the pre-infiltration levels. Based on a long-term simulation of 30-year of hourly data (precipitation and temperature), pre-development infiltration was found to account for approximately 40% of the total annual water budget. A subsequent Memorandum issued to the City on March 23, 2017, investigated water budget under post-development conditions where the high level analysis indicated that infiltration levels would be reduced from 40% (pre-development) to 19% (post-development without any infiltration measures) for a subdivision with an average imperviousness of 65%.

A preliminary assessment of the infiltration capability was carried out using PCSWMM assuming the implementation of the Etobicoke Exfiltration System (EES) within the BSUEA. The modelling methodology and assumptions as well as the key findings of this analysis were summarized in the Memorandum, issued to the City on March 23, 2017 (copy of the Memo attached). The infiltration assessment was conducted with the simulation of a test area that reflected the various types of residential usages as well as a separate simulation with a typical commercial block. Modelling of the test area was carried out using post-development infiltration rates that were reduced by a safety factor of 2.5 as per the recommendations of the Low Impact Development Stormwater Management Planning and Design Guide (Credit Valley Conservation Authority, 2010). Various development scenarios were simulated and corresponding post-development infiltrations estimated by PCSWMM. The resulting infiltrations have been summarized in the Table below for the various scenarios investigated:

Scenario	Infiltration Achieved
Existing Pre-development	40%
Post development with no EES infrastructure	19%
Rear yards and rear roof runoff only	30%
Commercial (30% roof area and only roof drainage to EES)	32%
All runoff captured into EES	65%

Based on the above simulation results, levels are anticipated to decrease from 40% under pre-development condition to 19% under post-development if no infiltration measures are adopted. Hence, to preserve the pre-infiltration levels, measures to promote infiltration such as the EES must be adopted. When servicing incorporates an EES sized to capture the 95th percentile (22 mm) storm, the infiltration under post-development conditions is increased to 65%. Consequently, the Memo recommended that an EES system be implemented within the BSUEA.

Concept and Demonstration Plans

A Concept Plan and Demonstration Plan (Figure 1 attached) were prepared by NAK Design Strategies and presented to the City as part of the Technical Advisory Committee (TAC) Meeting No. 4 (June 8, 2017). The various land uses and corresponding runoff coefficients (C-Factors) have been summarized in the Table below.

Land Use		**Area (ha)**	**Runoff Coefficient**
Residential	Back-to-back	2.8	0.70
	Single Family	29.8	0.58
	Condo	0.9	0.76
Roads	Local	15.7	0.69
	Collector	6.0	0.83
	Arterial	4.2	0.83
Parks		5.2	0.30
Park and Ride		2.6	0.87
School		4.4	0.75
Commercial		2.1	0.80
SWMF		5.4	0.69
Total		79.2	0.65

Impact of Salting Practice on Infiltration

One of the main recommendations of the Hydrogeological ECR was to preserve pre-infiltration levels by means of achieving distributed infiltration of “clean runoff” over the BSUEA. After further review and discussions of the salting practices within the City of Ottawa (refer to City of Ottawa Salt Management Plan, October 31, 2011), it was agreed that the EES could only be implemented along local roads given that collector and arterial roads rely more on salts as the abrasive agent. Consequently, the infiltration assessment was revisited assuming that the EES would only be implemented along local roads. A high level analysis was, therefore, carried out on a weighted basis to ascertain whether the pre-infiltration level of 40% can be preserved based on the attached Draft Demonstration Plan.

The infiltration assessment was conducted based on the following assumptions:

- No EES is placed on arterial and collector roads (refer to the attached revised Draft Demonstration Plan). As a result infiltration was excluded from these land use areas; however, assuming no infiltration on these areas is conservative as there will be some infiltration through the surface media along grass verges and pervious areas.

- Residential properties facing arterial and collector roads have only their rear yards and rear roofs draining to the EES on the adjoining local roads via rear yard catchbasins (refer to the attached revised Draft Demonstration Plan). A conservative assumption as there is likely to be some infiltration in the grassed/planted areas of front yards which is not counted in this analysis.

- All other residential areas and local roads are all serviced by EES and will achieve 65% infiltration as per the attached March 23, 2017 Memorandum.

- Along the commercial and institutional blocks, it is assumed that 30% of the block would consist of roof or other areas that would provide clean water runoff. Consequently, the analysis was conducted assuming that 30% of the blocks (roof areas) would have their own on-site infiltration system sized to capture and infiltrate the first 22 mm of clean runoff generated by the roofs. Runoff from the roofs in excess of 22 mm would be conveyed to the conventional system on the site. Runoff from the paved areas within those blocks would be detained on-site and treated by means of an on-site hydrodynamic separator (HDS). Once treated, runoff would be discharged pending its location to either a collector or arterial. This criterion is proposed as it is likely that salts might be used in the parking areas within those blocks and salted surfaces should only be discharge into sewer systems along collectors or arterials where no EES is present.

- Park blocks were not included in the test area simulation and so were assumed to maintain the post development infiltration level without any EES. This assumption is conservative as the post-development infiltration value of 19% is a result of higher impervious values across the site, which is not as great on the Park block, and, therefore, the infiltration across the pervious park will be higher.

- Infiltration for the Park and Ride block was excluded due to the small percentage of landscaped area. Any infiltration that will occur due to the small landscaped areas will be in excess of the percentages summarized below. Similarly, infiltration within the SWM blocks was excluded although the entire block will be landscaped. The exclusion of infiltration from the SWM blocks is based; i) very little infiltration along the relatively steep side slopes of the facilities, and ii) the higher groundwater table at both SWMF locations that will impact infiltration.

Based on the assumptions listed above, the areas and corresponding infiltration rates summarized in the following table was used in conducting the infiltration assessment (See Figures 2 and 3 attached).

Land Use		**Area (ha)**	**Runoff Coefficient**	**Infiltration Rate (%)**
Residential	Back-to-back	2.8	0.70	65
	Single Family[1]	23.5	0.58	65
		6.3	0.58	30
	Condo	0.9	0.76	65
Roads	Local	15.7	0.69	65
	Collector	6.0	0.83	0
	Arterial	4.2	0.83	0
Parks		5.2	0.30	19
Park and Ride		2.6	0.87	0
School		4.4	0.75	32
Commercial		2.1	0.80	32
SWMF		5.4	0.69	0
Total / Average		79.2	0.65	42

[1] Single Family blocks were modeled as part the revised Draft Demonstration Plan; blocks were split between local roads achieving 65% infiltration and collector/arterial, which achieves 30% infiltration due to the exclusion of the EES being installed on these types of streets.

Conclusion

Overall, with the above assumptions, the post-development infiltration across the BSUEA is expected to be approximately 42%. Therefore, the pre-development infiltration of 40% is expected to be met or slightly exceeded.

Re: BSUEA Infiltration System Maintenance Requirements

Date: June 22, 2017

Job No.: 26610

CC: Hugo Lalonde, MCIP, RPP
Land Development Manager
Minto Communities - Canada

Purpose of Undertaking

The future Barrhaven South Urban Expansion Area (BSUEA) will be developed as a standard suburb subdivision that will include the typical range of land usages; residential, commercial, institutional, parks and a Park and Ride facility. Based on the findings of the Study Area Existing Conditions Reports, the servicing of the Subdivision will need to be developed with measures that will promote infiltration to preserve the pre-infiltration levels. This Memorandum was prepared to address operation and maintenance requirements for a system that would be solely implemented on local roads and that has been described in previous Memoranda as capable to maintain pre-infiltration levels.

Background

On May 24, 2017, a meeting was held at the City of Ottawa (City) to discuss advantages and disadvantages associated with two (2) servicing systems that could be implemented within the BSUEA to promote infiltration of “clean runoff” to maintain pre-infiltration levels. The first part of the meeting consisted of a presentation that described both servicing systems promoting infiltration; the Etobicoke Exfiltration System (EES) and the Clear Water Collector (CWC) system that was implemented in the former City of Vaughan. During the latter part of the meeting, the advantages and disadvantages of both systems were discussed over with operation staff. Both of these systems have been discussed in a previous Modelling Memorandum and were presented to the City on May 24, 2017, a copy of the presentation has been attached.

During the May 24, 2017 meeting, the City has requested further information on the increased maintenance requirements for a stormwater conveyance system that would be designed with infiltration capabilities. From the Operation Staff, it was understood that the current maintenance program for traditional stormwater conveyance systems consist of cleaning of the storm sewers by jet flushing and, subsequently, proceeding with a closed circuit television (CCTV) inspection. This process is generally completed on a 20-year frequency. This Memorandum has, therefore, been prepared using as the baseline condition, the 20-year maintenance frequency.

Reported Maintenance Requirements of Infiltration Systems

The requirements of a maintenance program can be based on experience with previous installations of the EES or CWC systems. The EES was first designed in 1993 in the former City of Etobicoke, now part of the City of Toronto. The system was subsequently constructed later in 1993 and spanning until 1994 as part of the municipality’s road reconstruction projects, which included the installation of 2.1 km of the EES as a means to provide water quality enhancement for existing serviced areas. From the 2.1 km of EES installed, three (3) small sections were subject to monitoring and reporting post-construction; the Princess Margaret and Queen Mary’s Drive sites as well as the Braecrest site (refer to the Table below for details for each of the sites).

The first two (2) sites comprises of an EES with Goss traps similar to what is proposed for the BSUEA while the latter site, Braecrest, is closer to the CWC system with some minor modifications. Each system was designed with capacity to capture the runoff generated from the 15 mm - 1 hour AES rainfall event. For comparison purposes, the system now being proposed for the BSUEA is sized to capture, detain and infiltrate the runoff generated by the 22 mm - 4 hour rainfall event.

Monitoring Sites	Sewer Length (m)	Tributary Area (ha)
Princess Margaret	415	0.4
Queen Mary's Drive	443	13.3[1]
Braecrest	209	2.4

Post construction monitoring of the above-noted systems was initiated on completion of construction. Once completed, the systems were cleaned by jet flushing and subsequently inspected via CCTV. Follow up monitoring was undertaken for a two year period between 1996 and 1998 (SWAMP, 2004) and subsequently by the TRCA in 2013 (presentation slides attached). The 1996-1998 monitoring information was reported; however, the recent monitoring has not been formally reported other than the information attached to the presentation slides.

Prior to the 2013 monitoring, there was no further cleaning undertaken and the infiltration capability of the EES installations were found to be very similar to the original infiltration condition after 18 years of operation. At the Princess Margaret site, the infiltration capability was virtually found to be the same than the original one as the system's drawdown time was found to take approximately only ten (10) minutes longer than found during the 1998 monitoring program. At the Queen Mary site, the 2013 monitoring results were reported after the cleaning phase of the program occurred and it was found that the average water level drawdown rate approximately doubled following the clean out. The information presented by the TRCA (see attached) on the monitoring program suggested that the maintenance frequency would vary depending on design of the EES and catchment characteristics. As a result, inspections should be carried out preferably at least every 5 years to verify that drawdown time does not exceed 48 hours.

The Sustainable Technologies Evaluation Program, led by the TRCA, has prepared a publication entitled "Low Impact Development Stormwater Management Practice Inspection and Maintenance Guide" (PIMG), which includes a section devoted to underground infiltration systems; however, this section of the PIMG does not specifically address the EES or CWC. The PIMG (i.e., Table 7.28, with relative sections extracted below) suggests recommended frequencies for routine maintenance tasks including clean out of sediments (flushing and removal) once an accumulated depth of 100 mm has been reached. Based on inspection photographs of the EES during the 2013 monitoring (see the sewer inspection photographs in the attached TRCA presentation), approximately 100 mm of sediment or less had accumulated over the 20 year period; this accumulation excludes what was accumulated in the catch basins. In addition, the PIMG document recommends maintenance procedures such as removing accumulated trash and debris in the catch basins on a more regular basis, up to twice per year. This inspection work could evidently be combined with an inspection program.

The 2003 Stormwater Management Planning and Design Manual (SWMPDM),from the Ontario Ministry of the Environment and Climate Change (MOECC), provides some guidance on maintenance required for similar infiltration / pervious pipe systems such as the EES that is proposed. Table 6.1 in the Manual identifies the need for general inspection, removal of accumulated sediments, pipe flushing, catchbasin cleaning, trash removal and closing of the system for winter months when in a high salt / sand area. By installing the EES solely along local roads, the maintenance activity of closing the system for the winter months is not required.

According to the Manual, inspections should take place at a greater frequency for the first two years, after every significant storm event, to better understand the system's performance and to ensure that the perforated pipe system is operating as designed. After the first two years, the frequency of inspections could be reduced to annual inspections. In terms of frequency of sediment removal and cleaning, the Manual indicates that the system, including catchbasins, should be cleaned out if there is greater than one third the design depth of water in the catch basin sump 48 hours after a storm or if there is visible accumulation of sediment in the bottom of the catchbasin sump. Cleaning could be carried out by means of standard flushing, radial washing where the pipe is pressurized to force water through the perforations and cleaning out the sediment, or alternatively, jet flushing via a pressurized hose nozzle that directs water under high velocities into the perforations to remove the accumulated sediment.

[1] Of the 13.3 ha tributary area to the monitored section of the Queen Mary's Drive site, only 3.7 ha was immediately tributary to the EES sewers, the remaining area was from conventional sewer systems upstream of the site.

Measures to Reduce Maintenance Requirements

The design of the EES can be carried out by incorporating measures to reduce the maintenance frequency of the system. The measures include; i) using Goss traps in the upstream catchbasins as a pre-treatment measure, and ii) by rotating the angle of perforations to 45^{o} in the perforated pipe

Goss traps are used as standard in some Ontario municipalities including the City of Windsor and the City of Hamilton. They were used in the original sites of the EES in Etobicoke including those subject to the monitoring discussed above. This measure was adopted by the designers to: i) prevent debris collected in the catch basins from entering the perforated pipes, and ii) minimize oil trapped in the catch basins from entering the perforated pipes.

The alignment of the perforated pipe on its longitudinal axis is important in maximizing the efficiency of the system between maintenance visits and reducing the maintenance required. By placing the perforated pipes so that the perforations are not on the bottom of the pipe and are closer to the 4:30 and 7:30 locations on the clock, the perforated pipe will continue to function at full exfiltration capacity while sediment is deposited on the bottom. The need to clean out the sediment can be extended until sufficient sediment has built up to close up the angled perforations.

Recommended Maintenance Procedures and Frequency

Based on historical notes collected during the EES monitoring work, the review of the PIMG document (TRCA), the review of MOECC's SWPDM, best practices in operating conventional storm sewer systems and recent discussions held with stormwater professionals (refer to attached E-Mails), the following maintenance schedule is recommended:

Maintenance Schedule

Task	Frequency	Compared to conventional systems
Inspection of the system to ensure adequate operation including full drawdown of the sumps to below the perforated pipe invert level and ensuring that the plug part of the Goss trap is functioning properly by only allowing water from the deeper column to enter the catch basin lead	Once or twice per year - 48 hours or more after a significant storm event	Not required in conventional systems although could be considered good practice and preventative
Removal of accumulated trash and debris from sumps and grates	Twice per year	Best practice in conventional systems, part completed annually on grates with spring street clearing
Monitoring of the accumulated sediment depth in catch basins	Once a year	Best practice in conventional systems
Jet pressure wash and CCTV inspection of sewer and perforated pipes	At least every 20 years or when sediment levels reach 150 mm depth	As per conventional systems but only one sewer in conventional systems

From the table above, the increase in the maintenance requirements for an EES would consist of the following:

1. Annual or bi-annual inspections of the system at the manholes to confirm that drawdown is occurring within 48 hours following a storm event. If drawdown is not fully achieved after 48 hours, this could be indicative of the need to schedule flushing of the system; and

2. Jet pressure washing of the conventional storm sewer as well as the two (2) perforated pipes, from manhole to manhole, every 20 years. The increase in maintenance would be associated with the time to remove the mechanical plugs at the downstream end of the perforated pipes and to flush the perforated pipes. The mobilization cost will remain the same when compared to the single conventional sewer.

The additional maintenance requirement associated with item 2 above would not incur a significant time or a significant increase in costs. As previously noted, the time for the crew to mobilize would remain the same as what is anticipated for

a conventional system. The additional cost will be associated with jet pressure washing the additional length of sewers (i.e., perforated pipes) and potential for removing additional accumulated sediments, which is likely to occur in the perforated pipes when compared to conventional systems where the sediments can be washed away under self-cleansing flows.

An annual or bi-annual inspection of the EES at manholes would be the more costly of the two increased maintenance requirements as this task (checking drawdown time) is not currently completed and would require additional man-power (i.e, travel time and inspection time).

Estimated Maintenance Costs

A cost analysis of the increased maintenance is summarized below. In the event that the City has more recent costs for these tasks, then these would prevail. It should be noted that the costs listed below are in 2017 dollars.

- Anticipated number of manholes / catch basins for inspection: 250
- Time per manhole / catchbasin: 5 minutes
- Time for site: 21 hours
- Cost per hour: $53
- Total Cost for inspections: $1,120
- Annual cost: $2,240

- Anticipated length of EES sewer: 8.6 km
- Total Combo unit time: 86 hours
- Average cost per hour: $195
- Estimated cleaning cost: $16,770
- Estimated disposal: $500
- Annual equivalent cost: $870

Overall, the annual increase in cost for the City to undertake maintenance of the EES over the conventional storm sewer system is ±$3,500 a year on average for the anticipated sewer length within the CDP, excluding the aggregate extraction areas. It is considered that the increase in maintenance costs of the EES would be considerably less than the maintenance costs incurred with two wet pond structures, which is the alternative to provide similar levels of water quality control.

24 May 2017 1

Introductory Remarks

- Study Area
- Minto's sub-consultant Team
- Existing Condition Report
- Public Consultations/Workshops
- Six (6) CDP Options, 2 developed by Minto & 4 by the Public

24 May 2017 2

Process: CDP & MSS

- Community Design Plan process started in Fall 2015. Integrated planning act/EA project. Completion and acceptance of the CDP is anticipated Fall 2017.
- Field work for Existing Conditions Reports started in 2015, completed in 2016/2017 by various disciplines. Existing Condition Reports are considered 99% final, or sufficiently to advance to next steps.
- 2 public Open Houses have been held to date. A third open house is planned in June 2017 to present preferred plan and draft master documents.

24 May 2017 3

Hydrologeological Investigations, Findings & Recommendations

- The Hydrogeological Existing Conditions report provided a characterization of the existing geological and hydrogeological conditions at the subject site.
- The proposed CDP boundaries are largely contained within the esker boundaries (as mapped by Chapman and Putnam, 1984).
- The surficial materials generally consist of lodgment till/diamicton, silty fine sand and/or sandy silt with 15-25 m of overburden.
- Filed investigations included saturated field hydraulic conductivity measurements
- The Significant Groundwater Recharge Area (as mapped by the Mississippi Rideau Source Protection Plan, 2014) was confirmed to exist over the majority of the site.
- City of Ottawa Trail Road Facility has a Dewatering Pond to artificially alter groundwater flow direction to prevent leachate migration.
- Distributed infiltration systems were recommended to return clean captured water to the environment as close to the source as possible to prevent changes to the watershed contribution.

24 May 2017 4

Water Budget: General

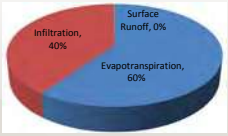
Natural watershed systems maintain a balance between precipitation, runoff to water bodies, infiltration to groundwater system, evaporation from water surfaces and transpiration from vegetation, completing the cycle back into atmospheric moisture and precipitation. The impact of urbanization on the natural hydrological cycle can be simplified graphically as follows:

24 May 2017 5

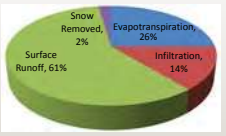
Water Budget: Summary of Findings

The water budget was assessed under pre- and post-development (uncontrolled) conditions over long-term simulation of 30-years of meteorological data. Simulation results have been synthesized graphically below:

Existing Pre-development



Uncontrolled Post Development



- Infiltration accounts for 40% and 14% of the total precipitation for the pre- and post-development (uncontrolled) conditions, respectively. An infiltration deficit of 26% is, therefore, anticipated if the subdivision excludes infiltration measures;
- Although surface runoff is virtually non-existent under pre-development (less than 0.5%), the model computed surface flows when precipitation depths exceeded a 1:5 year recurrence or when peak intensities were greater than a 1:2 year recurrence. Surface runoff increases to 61% under post-development (uncontrolled) conditions;
- Based on the above and MOECC's Interpretation Bulletin, storm servicing will include infiltration measures to preserve pre-development infiltration levels.

24 May 2017 6

Infiltration Measures to achieve Water Balance

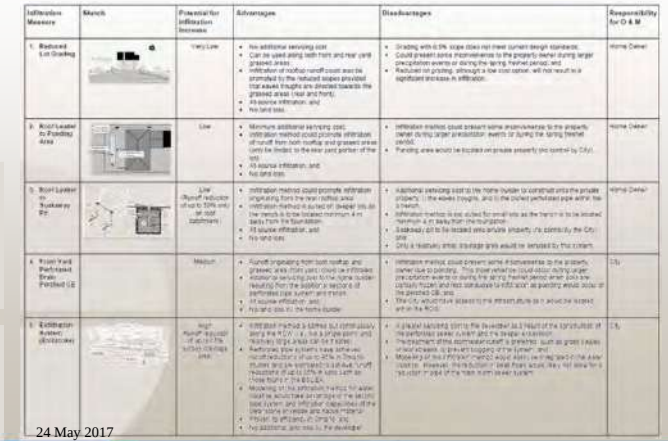
As per the recommendations of the Existing Condition Report (JLR, April, 2017), infiltration measures should have the ability to:

- Maintain or exceed pre-development infiltration levels over the overall BSUEA; and
- Maintain or exceed pre-infiltration levels by means of re-introducing clean water over each of the three (3) sub-watersheds.

Various infiltration measures were reviewed that would promote recharge of the shallow overburden aquifer. This review included the measures described in the MOECC 2003 Stormwater Management Planning and Design Manual (SWMPDM) and the CVC 2010 Low Impact Development Stormwater Management Planning and Design Guide (LIDSWMPDG).

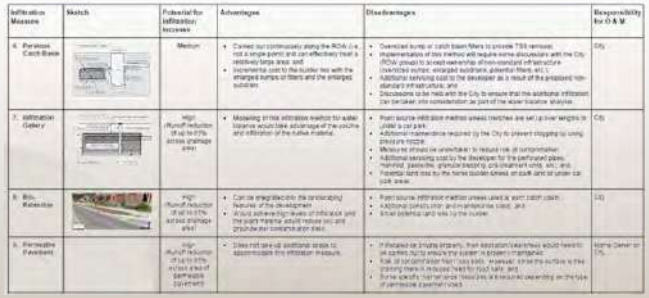
24 May 2017 7

Review of Infiltration Measures



24 May 2017 8

Review of Infiltration Measures

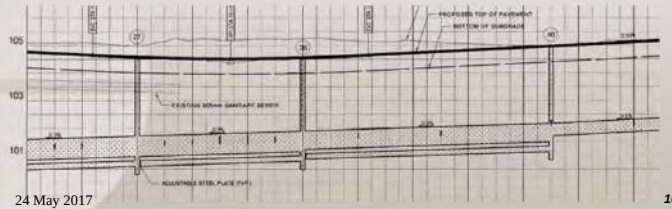


Following this review, the Etobicoke Exfiltration System (EES), including catchbasin filter trap, was recommended as the preferred infiltration measure due to the following advantages:

- Ability to achieve distributed infiltration of clean water over each of the three (3) sub-watersheds;
- Infrastructure fully contained on City owned lands; and
- Adaptability to be made inoperative in specific areas to minimize the infiltration of runoff impacted by road salts.

City of Ottawa Infiltration Measures

The City of Ottawa currently operates and maintains a similar infiltration system along Riverside Drive (MRC, 2012), Limebank Road to Hunt Club Road, Contract No. ISB07-5168

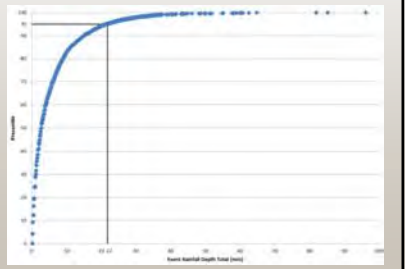


Etobicoke Exfiltration System: Planning & Sizing

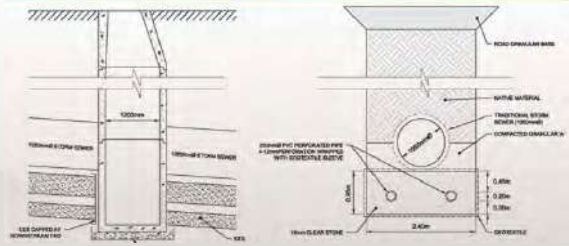
Steps in sizing the EES are based on the recommendations of the document entitled "Planning and Design Manual of the Etobicoke Exfiltration System for Stormwater Management, John Tran and James Li, Ryerson University":

- Design the storm sewer system in accordance with the local municipality (i.e., latest version of the Ottawa Sewer Design Guidelines, including Technical Bulletins);
- Carry out a statistical analysis by means of a rainfall event analysis of the hourly meteorological data collected at the Ottawa MacDonald Cartier International Airport;
- Identify the 95th percentile storm.

The analysis showed that a capture of 22 mm is equivalent to the 95th percentile storm.



EES Design Details

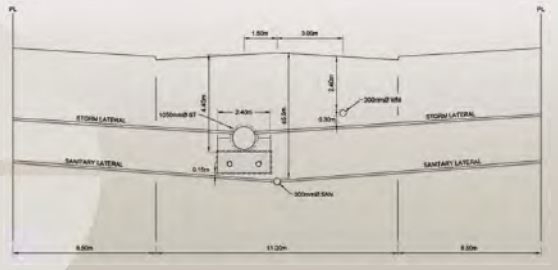


- Identify areas where a minimum distance of ±1 m can be provided between the high seasonal groundwater level and the invert of the EES;
- Develop the configuration of the granular envelope (19 mm clear stone - void ratio of 0.40) such that combined with the volume of the 2 perforated pipes (200 mm dia.) achieves the targeted volume;
- Target volume is 22 mm rainfall event capture. MOECC recommends a maximum target storage volume equal to the runoff from a 4 hour – 15 mm storm for pervious catch basins relying on exfiltration (refer to page 4-35 of the SWMPDM); and,
- The simulated granular envelope was defined as 2400 mm x 950 mm for test area.

Integration of EES

Review the configuration of the granular envelope and assess integration within ROW for various sewer sizes and depths

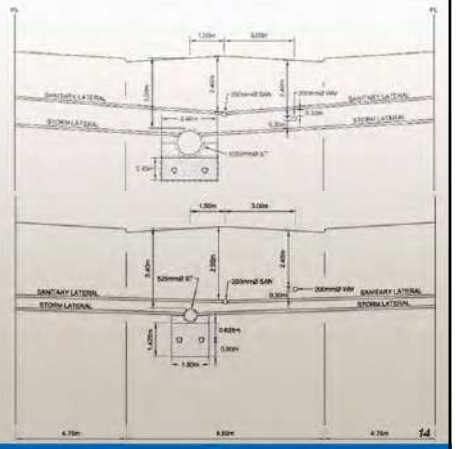
On **Collector** Road:
Sanitary sewer (200 mm dia. - 300 mm dia.) below the EES



24 May 2017 13

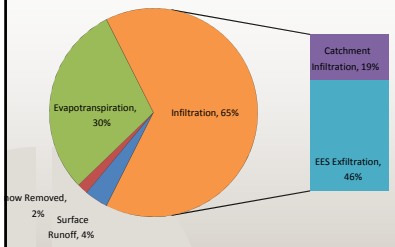
Integration of EES

On **Local** Road:
Sanitary sewer (200 mm dia.) above the EES



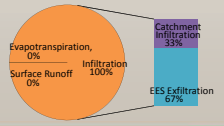
24 May 2017 14

EES: Simulation Results (test area)



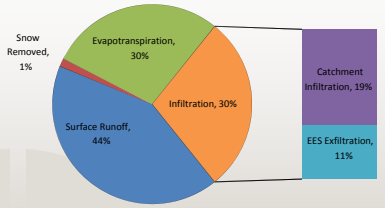
Residential and ROW lands draining to EES
30 years of continuous simulation
Residential lands Imperviousness based on average of residential types and lot configurations (average 56.8%)
Soil infiltration rates at 25.6 mm/hr, based on average rates across the site (excluding the pit areas), including factor of safety
Snow has been removed as part of the simulation based on 20% of impervious area being plowed and 80% of this snow being removed from the area

Same model as above, simulation of the 22mm - 4hour storm event
System sized to accommodate total runoff from 22 mm storm



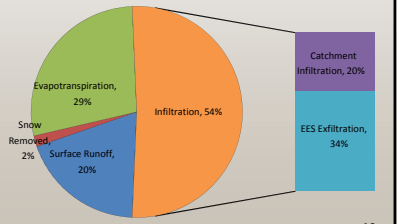
24 May 2017 15

EES: Simulation Results (test area)



Same model as before, under 30 years of continuous simulation
Only rear yards (including rear of roof) draining to EES

Same model as before, under 30 years of continuous simulation
All Residential and ROW lands draining to EES but EES **only operational between April 15 and November 15** annually



24 May 2017 16

EES: Simulation Results - Commercial

- Under a 22mm storm event, 125 m³ is captured and infiltrated in residential areas.
- Runoff from commercial areas were assumed to be conveyed to the EES within the ROW. Modelling approach assumed that commercial areas were to "mimic" the performance of the residential areas and infiltration be maintained or slightly exceeded. This criterion was adopted to prevent overloading of EES, which in turn, would decrease the level of service.
- 125 m³ amounts to 14 mm depth across 1 ha of commercial land at an imperviousness of 90%.
- In order to maintain the same level of service, servicing of the commercial sites should be developed to capture, detain and infiltrate on-site the first 10 mm of runoff : (22 mm less 14 mm = 8 mm, rounded to 10 mm).

EES: Installation

Before construction, all necessary erosion and sediment control measures must be installed to prevent sediment laden runoff from leaving the construction sites.

EES: Installation

1. Proceed with excavation of the trench using standard construction techniques.
2. Install filter cloth around the trench, stakes are to be used to hold the fabric along the vertical sides of the trench.
3. Install the clear stone bedding (19 mm) from the bottom of the trench to the design invert of the perforated pipes.

EES: Installation

4. Wrap the two (2) 200 mm dia. perforated pipes with filer fabric, lay both perforated pipes on top of granular bedding and place mechanical plugs on both upstream and downstream ends of the perforated pipes.
5. Install clear stone bedding (19 mm) over and around the perforated pipes until reaching the invert elevation of the traditional storm sewer.

EES: Installation

6. Install the storm sewer over the clear stone layer.
7. Install CB and CB leads, and connect CB leads to storm sewer.

EES: Installation

8. Install clear stone material around the storm sewer until reaching the top of the sewer

EES: Installation

9. Install and wrap filter cloth over the clear stone with an overlapping width of 1 metre.
10. Backfill the trench with suitable soils.

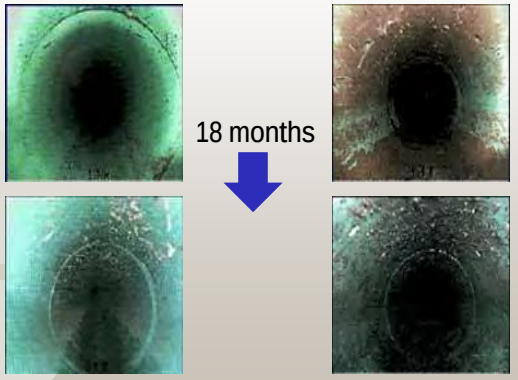
EES: Installation

11. Remove the mechanical plugs at the upstream end of each section of the system after all construction.

EES: Maintenance

Upstream

Downstream



EES: Maintenance

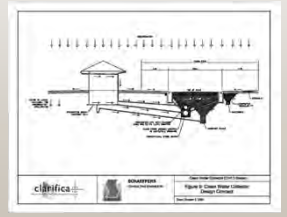
- Periodic maintenance is required
- Regular observation program would look at:
  - Visual evidence of overflows at sewer, water marks at the manhole, integrity of mechanical plug at the downstream manhole
  - Repair of minor deficiencies such as debris accumulation at the catchbasins including cleanout of any filter traps at the catchbasins
- Periodic Cleaning involves:
  - Removal of downstream mechanical plugs
  - Installation of temporary plug on upstream end of downstream pipe
  - High pressure water flusher inserted from downstream end to clean the walls of the perforated pipe
  - Debris flushed down to downstream manhole which is then pumped out by a vacuum truck
- Periodic Cleaning required approximately every ten years

Other Infiltration Measure: Vaughan's CWC

An alternate servicing method was used in Vaughan to promote infiltration and enhance groundwater recharge under post-development condition.

This system, referred to as the clean water collector (CWC), was implemented along the ROW and used as the infiltration measure to enhance ground water recharge.

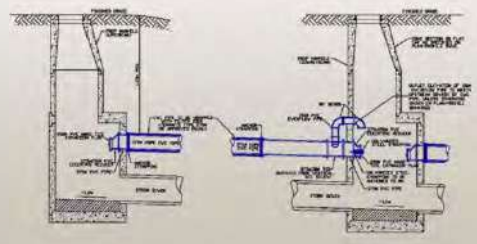
The CWC in Vaughan was sized to capture and infiltrate the first 22 mm of rain generated by rooftops only while events in excess of 22 mm could potentially overflow to the standard storm sewer.



Vaughan's CWC: Basic Components

The CWC system was comprised of 5 components:

1. The 375 mm diameter HDPE perforated pipe.
2. Solid connector to the downstream manhole.
3. Overflow system to downstream storm manhole.
4. Pipe plugs.
5. Lateral house connection leads.



Vaughan's CWC: How it functions

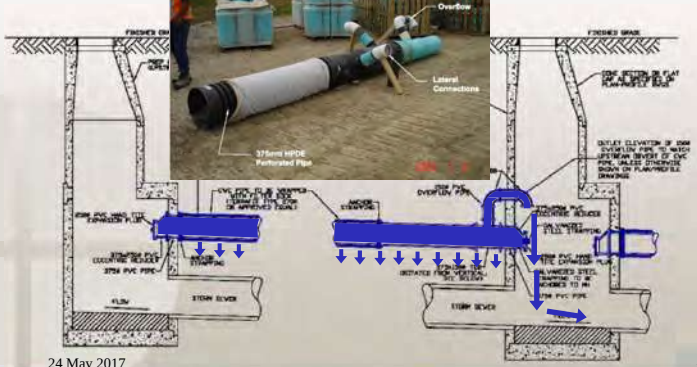
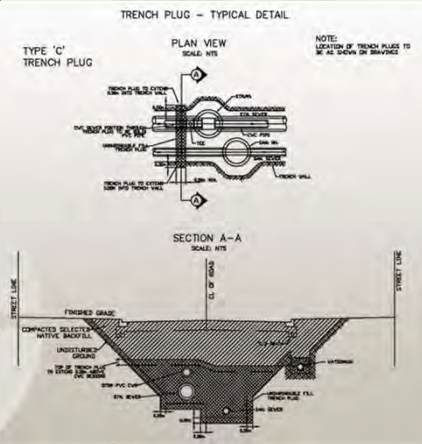
24 May 2017 29

Vaughan's CWC: How it functions



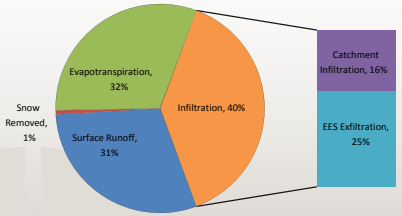
24 May 2017 30

Vaughan's CWC: Design Details



24 May 2017 31

Vaughan's CWC: Performance

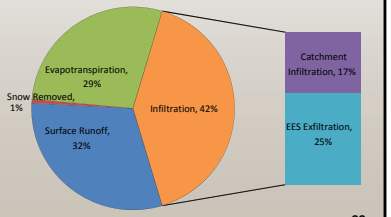


Same catchment parameters as EES under 30 years of continuous simulation

Only roof area draining to the CWC as per the configurations above

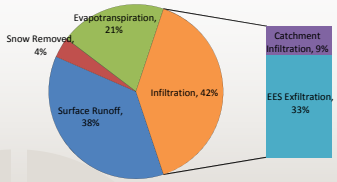
Same model as before under 30 years of continuous simulation

Roof areas and rear yards draining to the CWC system



24 May 2017 32

CWC: Simulation Results - Commercial



A separate CWC system would be needed for commercial areas:

- 1 ha of Commercial Land draining to CWC
- 30 years of continuous simulation
- 0.4 ha of Roof area at 100% Imperviousness and 0.6 ha of remaining area at 77% Imperviousness for an overall site C factor of 0.8
- Soil infiltration rates at 25.6 mm/hr, based on average rates across the site (excluding the pit areas) plus a factor of safety
- Snow has been removed as part of the simulation based on 80% of non-roof impervious area being plowed and 80% of this snow being removed from the area (conservative as it reduces the snow available for infiltration). No roof snow is removed.

24 May 2017 33

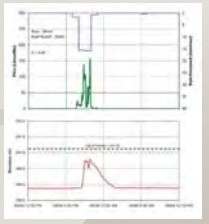
Vaughan's CWC: Monitoring

The CWC system was implemented at a Research Test Site in Vaughan for performance evaluation of the system via monitoring. The Test Site represented one lot and one half of the municipal ROW. The size of the trench was selected to provide, together with the perforated pipe, the volume required to capture the runoff from a 22 mm rainfall/snowmelt event over the roof area. Results of the monitoring was as follows:

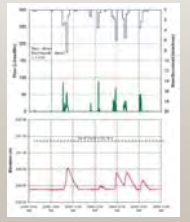
Event No. 1 (June 8, 2003) produced 34 mm of rainfall over ±4 hours; and

Event No. 2 (May 22, 2004) produced 45 mm of rainfall and spanned over 2 days.

Event No. 1 (June 8, 2003)



Event No. 2 (May 22, 2004)



24 May 2017 34

Vaughan's CWC: Monitoring

Monitoring of the Test Site has shown the following:

- For both events, the water levels in the trench responded quickly to inputs and also recovered quickly (refer to figure below);
- The fast system response time suggested effective performance of the pipe perforations, the storage utilization, and the infiltration into the surrounding soil significantly enhances the system performance during the same event or consecutive storms;
- Event No. 2 was comprised of several consecutive rainfall burst over short durations within 3 hours of each other (9.5 mm and 9.25 mm). The trench storage recovery occurs rapidly, even during relatively wet antecedent conditions;
- During the events, the water table did not rise to be measurable and the storage in the granular remained at about half of the storage capacity. This is indicative that:
  1. The Test Site did not infiltrate sufficient volume to affect the water table:
  2. The infiltration from all the surrounding pre-development areas was also not sufficient to affect the water table:
  3. There is efficient groundwater flow in the area – small changes in infiltration rates cause relatively rapid increases in groundwater flow.

24 May 2017 35

Infrastructure requirements - BSUEA

Key BBSS/ISR Objectives includes (page 3 of the September 13, 2016 presentation):

- Improve efficiency of land within the urban boundary
- Improving urban design and liveability
- Establishing appropriate Levels of Service and infrastructure standards that achieve economies in construction, maintenance and/or replacement costs
- Delivering infrastructure in more cost-effective ways.

24 May 2017 36

Infrastructure requirements - BSUEA

Water Quantity:

Design of the traditional storm sewer system in accordance to Technical Bulletin PIEDTB-2016-01; minor system capture to be set to the minimum 2-year capture or as required depending on the ROW designation

EES: capture and infiltrate 22 mm; this "loss" of runoff to the shallow aquifer will amount to 10% to 15% saving in quantity storage, which in turn, will have a footprint reduction to be assessed at the MSS.

CWC: capture and infiltrate 22 mm of all roofs; this "loss" of runoff to the shallow aquifer will amount to 5% to 10% saving in quantity storage, which in turn, will have a footprint reduction to be assessed at the MSS.

Infrastructure requirements - other constraints

The review of the Salting policy (Salt Management Plan, Appendix A, revision 3.2, October 31, 2011) shows the following:

On residential roads and lanes:

Requires that snow and ice be cleared and that ruts and/or potholes that may cause poor vehicle control be leveled off. Abrasive or de-icing materials are applied at intersections, hills and sharp curves:

Application ratio 5% by volume of CaCl, MgCl or multi chloride.

Given that a 5% salt mixture is only applied at intersections, hills and sharp curves, the impact of chlorides applied on local roads is found to be negligible. As a result, the EES with filtration system could be implemented on local roads.

Salt is applied on collector and arterial roads, which are limited in the BSUEA.

Quality Control

MOECC SWMPDM Table 3.2 requires:

Type	Imperviousness (%)	Storage Required (m^3/ha)	Total Storage (m^3)
Infiltration	66%	34	2,650
Wet Pond	66%	216	16,850

Storage provided in the EES is approximately 150m^3/ha on average, excluding the on-site capture required for ICI areas.

Vaughan's CWC vs EES

Criteria / Objective	EES	CWC
Maintains or exceed pre-development infiltration levels	✓	✓
Achieves distributed infiltration over 3 sub-watersheds	✓	✓
Achieves MOECC's Bulletin - Expectations for Stormwater Management	✓	✓
Additional maintenance of infrastructure is contained within ROW	✓	✓
Achieves water quality control on its own (80% TSS)	✓	✗
No need to be supplemented by other measure (wet pond or WQU)	✓	✗
Limits maintenance by the City to one water quality system	✓	✗
Can infiltrate runoff free of road salts	✓	✓
No operations required to switch between winter and summer operations	✗	✓

Vaughan's CWC vs EES

Criteria / Objective	EES	CWC
No additional land requirements for infiltration measure	✓	✓
Consistent with the City's Building Better Suburbs improved land efficiency project objective	✓	✓
Infrastructure fully contained on City lands	✓	✗
All maintenance responsibility of the City	✓	✗
Additional servicing cost to home builder to implement	✓	✓
No additional cost for each unit (home builder or home owner)	✓	✗
No additional servicing costs (deeper excavation)	✗	✓
No potential impact on life expectancy of standard sewer	✓	✗

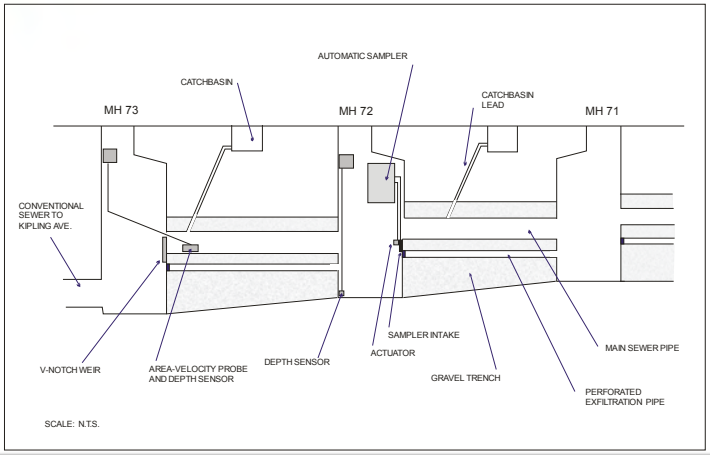
SWAMP Study
Princess Margaret Monitoring Lay-out



SWAMP Study
Princess Margaret Results: 1996 - 1998

- No overflows in 1996 – 2 rain events above 15 mm
- No overflows in 1997 – 7 rain events above 15 mm
- 3 events caused overflow in 1998, no overflow from 2 events > 15 mm
  - 20.2 mm followed by 3.6 mm two days later
  - 14.9 mm followed by 11.9 mm the same day (26.8 mm total)
  - 15.3 mm, high intensity (9.7 mm in 5 minutes)
- 98% of rainfall runoff infiltrated
- Mean TSS concentrations in sewer were 164 mg/L and 81 mg/L in summer and winter, respectively

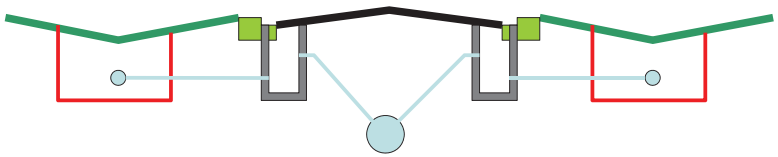
General Conclusions

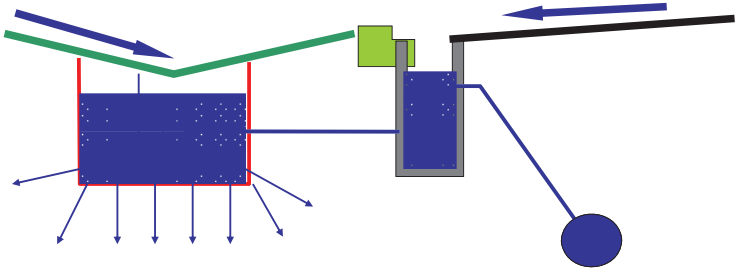
- PM exfiltration system continues to meet design target
- Overflows often occurred due to limited through put capacity rather than inadequate trench storage availability
- Higher density of perforations and/or larger pipes to facilitate rapid conveyance of runoff into trench
- Improved pre-treatment within the catchbasin or manhole would help reduce clogging of perforated pipes
- Trench dams preventing flow between trench sections may need further consideration
- Maintenance frequency variable depending on design and catchment characteristics – inspections required every 5 years

Other Exfiltration System Designs

Exfiltration system, North York



Exfiltration system, North York



Exfiltration Systems, Ottawa

- Curbless system with pretreatment through a grass swale
- After 20 years, and limited maintenance, the system continued to function very well

Subject: Re: EES Maintenance Requirements Query

Hi Bobby,

We did a maintenance inspection and evaluation of the EES that looked a two system. In the Ryerson slides, the discussion is represented by two drawdown curves for Princess Margaret Blvd and Queen Mary. In a nutshell, this is what we found:

1. Princess Margaret Blvd. Monitored in the 1990s, returned in 2013 to monitor again. Drawdown of water into the exfiltration system (representing infiltration_ after large events was essentially the same as was monitored initially and again by SWAMP in the 1990s. This was surprising as we have no record of the system ever being maintained. There was some minor buildup of sediment in the perforated pipes and manhole, but surprisingly little (pictures provided in slides).

2. Queen Mary System. This one was located in a narrow residential street with a dense canopy of trees (unlike PM Blvd, which was more open, and a larger street overall). There was also some evidence that the system had a conventional sewer connection to the system along Prince Edward Drive, although this was not confirmed by our team. This one was also not maintained since installation, and showed buildup of sediment in the manhole and pipes, but was still infiltrating as shown by the draw down curves. We paid for a clean out of one leg of the perforated pipe at around 2 K, and only one of the two pipes, then compared drawdown before and after. We found that the drawdown rate (i.e. infiltration) doubled after cleanout of one pipe, so if both pipes were cleaned you may expect even better performance. Most of the sediment that collected in the pipes was very coarse and removable with readily available equipment.

Bottom line is that these systems seem to be very robust, and probably don't need cleaning more than once every 5 years or so (inspections should be done annually). The design of the EES is not optimized because the catchbasins do not provide sufficient pre-treatment of runoff. Installing a CB shield or other type of scour prevention type device would help retain more of the sediment/leaf litter in the catchbasin, the latter of which are cleaned annually or biannually. There are screens or other devices that may be added to keep the coarse sediment out of the EES.

We have not had a chance to write up this maintenance evaluation properly in a technical brief. However we do have our LID inspection and maintenance guide, that provides detailed advice on needs across a range of LID type BMPS. It is available at: http://www.sustainabletechnologies.ca/wp/home/urban-runoff-green-infrastructure/low-impact-development/low-impact-development-stormwater-practice-inspection-and-maintenance-guide/

Hope that helps

Tim

Subject: EES Maintenance Requirements Query

Hi Tim

We have been undertaking some investigations into Stormwater infiltration systems, specifically the EES or similar CWC used in Vaughan. We came across your July 2015 presentation made as part of the seminar on the EES at Ryerson University.

Our land developer client is progressing on developing a 120 ha site and is required to maintain pre to post infiltration due to the underlying SGRA and associated esker. We are working with the City in identifying an infiltration measure which would be appropriate and the EES seems to be attractive. The hurdle we have is that the long term maintenance requirements of such a system seem to be relatively unknown. I was just wondering if there had been any further work following your presentation on the maintenance requirement of an EES network or if you have any contacts in the local municipalities who are looking after such a system?

Any advice or contacts would be appreciated. Any questions let me know.

Thanks
Bobby

Subject: RE: EES and CWC Maintenance Requirements Information

Hi Bobby,

I ran into Muneef the other day and he had given me a heads up I may be contacted regarding the EES. Yes I had the pleasure of having John Tran as a mentor as I did my masters on modelling the EES. While I didn't do any research on the maintenance, I do know that the design allows for easy clean-up of any sediment/debris within the perforated pipes by power flushing the sediment down the pipes (downstream plug removed) and into the downstream manhole to be removed by vacuum. During the 20+ years that it's been in use at the Princess Margaret Blvd and Queen Mary Dr sites, I believe there was no maintenance done to it until perhaps recently? When Tim was doing monitoring work (just a couple years ago), I believe he also took a look at the state of the system and possibly cleaned it out too? You'll have to verify with him, but I recall hearing that the Queen Mary site after all those decades had gotten quite a bit of debris/leaves because the downspouts aren't disconnected in that area and there were no clean outs.

Also, the location of the perforations along the pipe are key to maintaining long term performance. If the perforations are rotated 45 degrees to the vertical/horizontal, it allows for sedimentation on the bottom of the pipe without losing any perforations, until it gets really full.

Dr. James Li from Ryerson University was/is also involved with the EES. There is a draft manual of the EES on his university website that may be of help: http://www.civil.ryerson.ca/seminar/Papers/Draft%20Design%20manual%20of%20EES%20by%20Tran%20and%20Li%207-24-2015.pdf.

Hope that was of use. If you have any other questions please let me know.

Take care,
Sabrina

Subject: EES and CWC Maintenance Requirements Information

Hi Sabrina

I have been passed on your contact details by other contacts and I was hoping you would be able to help. We are currently working on a subdivision for a land development client which is located over an esker and the City and Conservation Authority are keen on retaining infiltration over the area. We have been researching various means of

achieving infiltration and have identified the Etobicoke Exfiltration System (EES) and the Clearwater Collection system (CWC), which was used in the City of Vaughan, as possible solutions.

One of the hurdles we are facing in using either of these systems is the relative unknown in terms of maintenance requirements for these systems. I believe that you worked with the late John Tran in the EES and I was wondering if you had any follow up research on maintenance of the systems. We have already been in contact with Tim Van Seters at the TRCA and he pointed us to his work done in terms of the monitoring. Any other knowledge you have or any documents you can point us to would be greatly appreciated.

Thanks
Bobby

Appendix G

PCSWMM Model Inputs and Results

Appendix G – PCSWMM Model Parameters

The following sets out a description of each of the parameters used in the modelling. Any differences from the below at any of the specific elements are noted in the description in the model. Two types of modelling were used and are described below.

The event modelling is used to provide the analysis of the storm major and minor system design for HGL and capacity assessments. The continuous simulation modelling is used to determine the long term water budget of the BSUEA.

All surface and infrastructure elements should be present in the event simulation. Only those elements which impact the soil infiltration affect the continuous simulation model and to save run time the continuous simulation model has much of the sewer network and major system network removed. The EES system elements are maintained in the continuous simulation model as they will provide addition infiltration into the soils and groundwater table.

G1.0 Subcatchments

G1.1 General Parameters

Parameter	Units	Description / Values
Name	-	The name of the subcatchment is linked with the minor system section to which the runoff is directed.
Tag	-	No tags have been used for the subcatchments.
Rain Gauge	-	The storm type selected for the model run. In the event simulations the following storm files are used: Distribution — Return Periods 3 hour Chicago — 1:5, 1:10, 1:100 24 hour SCS — 1:5, 1:10, 1:100 Under the continuous simulation the 30 year data was used from Environment Canada weather stations at Ottawa Macdonald-Cartier International Airport and the Experimental Farm. The same long term rainfall was used in the Existing Conditions Report (Appendix B).
Outlet	-	The downstream major system node to which the subcatchment drains.
Area	ha	The area is calculated internally by PCSWMM and the value varies.

Parameter	Units	Description / Values
Width / Flow Length	m	For lumped catchment areas representing predominately residential land uses the width parameter is set at 225 m/ha as per the OSDG. Where the catchments are for non-residential land uses the width is the area of the catchment divided by the runoff flow path.
Slope	%	All slopes are a representative 2%.
Imperv	%	The following percent impervious values have been used: **Land Cover** — **Impervious (%)** Majority Residential Catchments — 67.143 Arterial / Collector Roads — 86 Schools — 79 Commercial — 93 Park and Ride — 93 The value for residential areas is based on an average for residential land cover catchments across the site.
N Imperv	-	A constant of 0.013 is selected as the Manning's N for impervious surfaces such as roads, sidewalk and parking areas. The value is representative of smooth impervious surface as per Table 3-5 of the EPA Storm Water Management Model Reference Manual Vol I – Hydrology (EPA, 2016).
N Perv	-	A constant of 0.25 is selected as the Manning's N for pervious areas. The value is representative of light to tense turf land cover as per Table 3-5 of the EPA Storm Water Management Model Reference Manual Vol I – Hydrology (EPA, 2016).
DStore Imperv	mm	A constant of 1.57 mm is used as the impervious depression storage as per the OSDG Section 5.4.5.4.
DStore Perv	mm	A constant of 4.67 mm is used as the impervious depression storage as per the OSDG Section 5.4.5.4.

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Zero Imperv</td><td>%</td><td>Across areas of water it is considered that there is no depression storage. For the catchment areas representing SWMFs the approximate coverage of the SWMF is used for the percent of zero impervious.</td></tr>
<tr><td>Subarea Routing</td><td>-</td><td>The constant ‘PERVIOUS’ is entered to simulate the subarea of impervious surface, such as the rear part of roofs, which may flow over pervious areas prior to discharging to the outlet of the subcatchment.</td></tr>
<tr><td>Percent Routed</td><td>%</td><td>The percentage of impervious area which is routed across the pervious area. The percentages are area weighted in PCSWMM based on the following impervious types:

Land Cover — Percent Routed
Residential catchments — 20
Arterial / Collector Roads — 0
Parks / SWM — 100
Schools — 0
Commercial — 70
Park and Ride — 0</td></tr>
<tr><td>Drying Time</td><td>days</td><td>The time for a fully saturated soil to completely dry is set at 7 days though this is not used in design event analysis.</td></tr>
</table>

Parameter	Units	Description / Values
Infiltration	-	The standard Horton infiltration coefficients as per the City's OSDG are used for the event modelling. For long term simulations the coefficients are as per the results of the Paterson field testing of Hydraulic Conductivity. See section B6.1.1 of the Existing Conditions Report (Appendix B) for a description of how the saturated field hydraulic conductivity was transferred into infiltration rates. For long term simulation the values have been reduced by a factor of 2.5 as per guidance from the Credit Valley Conservation Authority and Toronto and Region Conservation Authority Low Impact Development Stormwater Management Planning and Design Guide Appendix C. The Guide states that a safety correction factor of 2.5 should be applied where there is a ratio between the mean measured infiltration rates of 1 or less. The safety factor represents the potential loss of infiltration due to compaction during construction and gradual accumulation of fine sediments over the lifespan of the BMP.
Decay Constant	hr^{-1}	City of Ottawa standard value of 4.14 is used.

The parameters Curb Length, LID Controls and Erosion are not used in the model.

G1.2 Snowmelt

Used in the continuous simulation modelling only.

Parameter	Units	Description / Values
Dividing Temperature	°C	The temperature below which precipitation will fall as snow. Generally accepted as being 0°C. Value: 0
Snow Capture Factor	Fraction	It is assumed that the data from Environment Canada has captured all snowfall in the gauges. This factor can be used to increase snowfall where the gauges may not be accurate. Value: 1.0

Parameter	Units	Description / Values
ATI Weight	Fraction	Applied over the entire subwatershed, the ATI weighting factor is an indication of the thickness of the surface layer of snow. A low value will indicate a thicker surface layer with weighting to temperatures over the previous week while a value closer to 0.5 will indicate a normal surface layer. The lower the ATI Weight the snow will cool and warm more slowly. A value of 0.5 has been found to give reasonable results in watersheds and has been used here. Value: 0.5
Negative Melt Ratio	Fraction	The effect of the heat transfer during non-melt periods and the standard value is used. Value 0.6
Elevation above MS	m	The elevation will affect atmospheric pressure for the melt calculations. Value: 107
Latitude	°	The latitude will dictate the sunrise and sunset times in temperature calculations. Value: 45.0
Longitude Correction	minutes	Used to correct for in separation of the position of site versus the meridian of the standard time zone. This will have negligible effects. Value: 0
Melt Coefficients	mm/hr /°C	The Melt Coefficient has been taken from the AES snowmelt equations for southern Ontario (MNR Technical Guide Flooding Hazard Limit, 2002). The AES equations have a melt coefficient of 3.66 mm/day/°C for mean daily air temperatures. This equates to 0.1525 mm/hr/°C. Value: 0.153
Base Temperature	°C	The base temperature at which the snowpack will melt has been assumed as 0°C. A lower value could be used for rooftops where there will be heat transfer through the roof. Value: 0

Parameter	Units	Description / Values
Fraction Free Water Capacity	Fraction	Since snow is considered a porous medium some of the melt water may be contained within the snow pack. The fraction of the free water capacity is the fraction of the snow pack void space which will retain meltwater. This fraction is normally less than 0.1 and 0.05 has been used here to represent a deep snowpack. A value of 0.25 may represent a shallow slush layer. Value: 0.05
Initial Snow Depth	mm	The initial snow depth on the site is considered as zero. Value: 0
Initial Free Water	mm	Since there is no initial snow depth the initial free water has also been considered as zero. Value: 0
Depth at 100% Cover	mm	The snowmelt model assumes that there will always be a depth of snow above which there will be 100% coverage of the snow, even in areas which may be affected by shading, drifting of topography. Typical depths are 25 mm to 100 mm. Since the area is relatively open with limited shading then the lower end of the value range has been used. Value: 25
Fraction of impervious area that is plowable	fraction	It is assumed that for the developed areas where the 'future' snow pack is used that 20% of impervious areas will be plowed. Value: 0.2 For the area that is plowable the following parameters are applied: Depth at which snow removal begins (mm) 25.4 Fraction transferred out of the watershed 0.8 Fraction transferred to the impervious area 0.1 Fraction transferred to the pervious area 0.1 Fraction transferred into immediate melt 0.0 Faction moved to another subcatchment 0.0

Parameter	Units	Description / Values
Areal Depletion	Fraction	The areal depletion curve represents the area of snow cover for depths of the snow less than the depth at 100% coverage. Natural areal depletion curves are suggested by the software and are used here.

G1.3 Groundwater

Used in the continuous simulation modelling only.

Parameter	Units	Description / Values
Aquifer Name	-	Name of the aquifer representing soil conditions. Four Aquifers were created based on different soil conditions from OSG mapping. Only two of the aquifers are used within the study area, A and B. Aquifer / Description / Clay (%) / Sand (%) A / Sand / 5 / 92 B / Sandy Loam / 10 / 65 C / Sandy Clay Loam / 28 / 60 D / Clay Loam / 34 / 33
Receiving Node	-	Name of the receiving node for groundwater outflow to baseflow. This is based on the groundwater subwatershed delineation.
Surface Elevation	m	Elevation of the ground surface for the subcatchment was averaged from the Patterson report. Value: 107
Coefficients		The coefficients were set for the saturated groundwater zone to represent a storage reservoir where outflow is linear proportional to the water table depth without surface water interaction. It was considered that the nearest open water channels were sufficiently far to have negligible impact on groundwater levels. The groundwater equation used is: $f_G = A1\ (d_L - h_{sw})$ Where: f_G = groundwater flow d_L = depth of the lower saturated subsurface zone h_{sw} = height of surface water above the bottom of the groundwater zone A1 = Calibration factor (estimated at 0.05)

Parameter	Units	Description / Values
		Value: 0.05
Surface Water Depth	m	Set as 0.5 metres to allow flow from the water table to surrounding watercourses. Value: 0.5
Initial Elevation	m	Initial elevation of the water table Value: 95.5
		All other parameters used as per the receiving node or aquifer

G1.4 Aquifer

Used in the continuous simulation modelling only.

Parameter	Units	Description / Values
Porosity	Fraction	The following values were used for the volumetric water content of the soil at saturation (i.e. volume of water per total volume): **Soil Group** **A** **B** **C** **D** Porosity 0.436 0.450 0.432 0.472 *(Source: SPAW Calculator)*
Wilting Point	Fraction	This is soil moisture contact at which plants cannot obtain sufficient moisture from the soil to meet transpiration requirements and they will die. It is roughly equivalent to the moisture content of soil at 15 atmospheres. The following values were used: **Soil Group:** **A** **B** **C** **D** Wilting Point: 0.050 0.081 0.183 0.213 *(Source: SPAW Calculator)*
Field Capacity	Fraction	Considered to be the amount of water a well-drained soil holds after free water has drained off. The following values were used: **Soil Group:** **A** **B** **C** **D** Field Capacity: 0.094 0.179 0.283 0.350 *(Source: SPAW Calculator)*

Parameter	Units	Description / Values
Conductivity	mm/hr	Within the Aquifer Parameters, the soil saturated conductivity is a governing parameter of the percolation rate between the upper unsaturated soil layer and the lower saturated soil layer. This is not the same as any hydraulic conductivity used for the surface infiltration. The values have been selected from the SPAW calculator and are: **Soil Group:** **A** **B** **C** **D** Conductivity (mm/hr): 114 50.3 7.8 4.6 *(Source: SPAW Calculator)*
Conductivity Slope	-	Conductivity slope measures the rate at which a soil's hydraulic conductivity decreases with decreasing moisture content. Regression analysis has shown it can be estimated with the following relationship: Conductivity Slope = 0.48(% Sand) + 0.85(% Clay) Based on this relationship the following values were used: **Soil Group:** **A** **B** **C** **D** Conductivity Slope: 48 40 53 45
Tension Slope		Used for backward compatibility in the software and not used in this model
Upper Evaporation Factor	Fraction	This factor determines the fraction of available subsurface evaporation rate used in the upper subsurface zone (compared to the lower subsurface zone). A higher evaporation rate is associated with looser soils, lower water table elevations and shallow root zones. It was assumed that in all soils 80% of the available subsurface evaporation would be used in the upper zone due to the depth of the water table. **Value: 0.8**
Lower Evaporative Depth	m	The depth of the lower subsurface zone which can be used for evapotranspiration should be approximate to the expected average depth of root penetration. This does not impact this type of model but the following values were used: **Soil Group:** **A** **B** **C** **D** Evaporative Depth (m): 1.5 2.4 3.0 5.2 *(Source: Shah et al 2007 from EPA 2015)*

Parameter	Units	Description / Values
Lower Groundwater Loss Rate	mm/hr	This is the rate of percolation from the lower subsurface zone to a deep aquifer and is approximate to the rate at which the water table elevation will drop over a prolonged dry period. The saturated hydraulic conductivity of a compacted clay soil was used in all cases however it does not affect the model. **Value: 0.004**
Bottom Elevation	m	The elevation of the bedrock as averaged from the Patterson 2016 report. **Value: 85**
Unsaturated Zone Moisture		The moisture content of the unsaturated upper subsurface zone at the start of the simulation. Cannot be less than the wilting point and cannot be more that porosity. Assumed to be an approximate value between the wilting point and porosity fractions. **Soil Group:** **A** **B** **C** **D** Evaporative Depth (m): 0.25 0.22 0.32 0.35

G2.0 Link Elements

G2.1 Conduits

Parameter	Units	Description / Values
Name	-	The links are generally named as 'Upstream Manhole – Downstream Manhole'.
Inlet Node	-	Upstream node of the link element.
Outlet Node	-	Downstream node of the link element.

Parameter	Units	Description / Values
Tag	-	The following tags are used in the model to classify the links: **Tag** — **Classification** Storm Sewer — BSUEA minor system Street — BSUEA major system QP_Storm_Sewer — Quinn's Pointe minor system QPLow_Storm_Sewer — Quinn's Pointe minor system in the low lying area connected to Greenbank Road. GB_Storm_Sewer — Greenbank Road minor system
Length	m	Length is auto-calculated in PCSWMM
Roughness	-	The roughness coefficient of 0.013 is used for all minor system conduits. Where the conduit is part of the major system the roughness is contained within the transect and this value is not read by the model.
Inlet Elevation	m	Elevation of the upstream end of the link.
Outlet Elevation	m	Elevation of the downstream end of the link.
Initial Flow	m^3/s	No initial flows are set in the model
Flow Limit	m^3/s	No flow limits are set in the model
Entry Loss Coeff.	-	For minor system links in the BSUEA and Greenbank Road no entrance losses are applied. The minor system losses for the Quinn's Pointe links are as per the original XPSWMM model for the subdivision. For the connection between Pond 2 and the minor system the entry loss is representative of a concrete pipe with headwall inlet as per Table A.11 of the SWMM 5.0 User Manual. No losses are applied to the major system.

<table>
<tr><th>Parameter</th><th>Units</th><th>Description / Values</th></tr>
<tr><td>Exit Loss Coeff.</td><td>-</td><td>For the minor system the entry loss coefficient is based on the angle of change in flow direction at the downstream manhole as per the values below (read from City of Ottawa Sewer Design Guidelines Appendix 6-B).

<table>
<tr><th>Angle °</th><th>Loss Coeff.</th><th>Angle °</th><th>Loss Coeff.</th></tr>
<tr><td>0</td><td>0.02</td><td>50</td><td>0.46</td></tr>
<tr><td>10</td><td>0.05</td><td>60</td><td>0.64</td></tr>
<tr><td>20</td><td>0.12</td><td>70</td><td>0.84</td></tr>
<tr><td>30</td><td>0.21</td><td>80</td><td>1.07</td></tr>
<tr><td>40</td><td>0.32</td><td>90</td><td>1.32</td></tr>
</table>

The minor system losses for the Quinn’s Pointe links are as per the original XPSWMM model for the subdivision.

Exit losses from the minor system into open water, e.g. at Ponds, is 0.5 where the pond level is low compared to the sewer HGL and 1.0 where the sewer is low in the pond.

No losses are applied to the major system.</td></tr>
<tr><td>Average Loss Coeff.</td><td>-</td><td>The average loss coefficient is not used in this model.</td></tr>
<tr><td>Seepage Rate</td><td>mm/hr</td><td>There is no seepage applied to conduits in this model.</td></tr>
<tr><td>Flap Gate</td><td>-</td><td>No flap gates are used in the model.</td></tr>
<tr><td>Cross Section</td><td>-</td><td>Minor system links conduits are circular to represent pipes.

Major system conduits are Irregular and use the transect listed in the parameter below.</td></tr>
<tr><td>Geometry</td><td>M</td><td>The geometry of the conduit for cross sections other than irregular. The single value is the diameter of the conduit.</td></tr>
<tr><td>Barrels</td><td>-</td><td>No multiple barrel conduits are used in the model and the value is 1.</td></tr>
<tr><td>Transect</td><td>-</td><td>The cross section of the major system conduit, a typical road cross section based on the road classification.</td></tr>
<tr><td>Shape Curve</td><td>-</td><td>Not used in this model</td></tr>
</table>

Parameter	Units	Description / Values
Culvert Code	-	For the conduits collecting flows from Pond 1, the code is used to allow analysis for inlet control conditions using the FHWAA-HDS-5 method. The culvert codes are as per Table A.10 of the EPA SWMM User's Manual and represents a concrete circular culvert with headwall.

G2.2 Weirs

Weirs are generally used in the model to represent the overland flow paths in the major system network and transfer the flow from surcharging of street sag storage to a downstream node. In detailed design these will be replaced with conduits to simulate major system routing, however the weirs are used here at a high level to provide connectivity in the model.

Parameter	Units	Description / Values
Name	-	The links are generally named as 'Upstream Manhole – Downstream Manhole'.
Inlet Node	-	Upstream node of the weir element.
Outlet Node	-	Downstream node of the weir element.
Tag	-	Not tagged.
Type	-	All weirs in the model are traverse weirs.
Height	m	The height of the weir has been set to ensure that ponding at the upstream street sag storage node is no greater than 350 mm.
Length	m	The length of the weir is set at 8.5 metres to approximate the width of overland flow paths which will vary within each lumped drainage area.
Side Slope	m/m	No side slopes are applied.
Inlet Offset/Elevation	m	The inlet offset or elevation of the weir has been set to ensure that ponding at the upstream street sag storage node is no greater than 350 mm.
Discharge Coeff.	m^3/s	The discharge coefficient of 1.67 is used in the model to represent a broad crested weir.

Parameter	Units	Description / Values
Flap Gate	-	No flap gates are applied to weirs in the model.
End Contractions	-	No end contractions are applied to weirs in the model.
End Coeff.	m^3/s	No end coefficient losses are applied to weirs in the model.
Can Surcharge	-	Weirs are allowed to surcharge.

G2.3 Outlets

Outlets have been used to represent the combined inlet capture from the lumped drainage area.

Parameter	Units	Description / Values
Name	-	Outlet links are named the same as the subcatchment from which the flow is captured.
Inlet Node	-	Upstream node of the outlet link, the major system node.
Outlet Node	-	Downstream node of the outlet link, the minor system manhole at the upstream end of the receiving link.
Tag	-	No tags are used
Inlet Offset/Elevation	m	The outlet upstream offset or elevation is set at that of the upstream major system node invert.
Flap Gate	-	No flap gates are used on the outlets
Rating Curve	-	A three point rating curve is developed for each outlet link and the rating curve is named the same as the outlet link. The rating curve is set to control the outlet flow to the required inlet capture rate. The set inlet capture rates are summarized in the design criteria section of the report.

G2.4 Orifices

Orifices are used to represent the control device at the outlet of a pond or the ICD which will be placed at the downstream end of the Quinn's Pointe system to control flows from Pond 1.

Parameter	Units	Description / Values
Name	-	The links are generally named as 'Upstream Manhole – Downstream Manhole'.
Inlet Node	-	Upstream node of the weir element.
Outlet Node	-	Downstream node of the weir element.
Tag	-	Not tagged.
Type	-	All orifices in the model are side orifices.
Cross Section	-	All orifices in the model are circular orifices.
Height	m	The height of the orifice is the opening diameter.
Width	m	The width parameter is not used for circular orifices.
Inlet Offset/Elevation	m	The inlet offset or elevation of the orifice is set at the elevation of the upstream node.
Discharge Coeff.	m^3/s	The discharge coefficient of 0.65 is used.
Flap Gate	-	No flap gates are applied to orifices in the model.
Time to Open/Close	-	Time to open/close a gated orifice is not used in the model.

G3.0 Node elements

G3.1 Junctions

Junction node types are used for major system nodes along minor system conduits. Minor system manholes are represented using storage nodes (see section A1.1).

Parameter	Units	Description / Values
Name	-	Nodes are named after the subcatchment draining to the node.
Tag	-	Minor system junctions are tagged 'Street'.

Parameter	Units	Description / Values
Inflows	-	No junctions have additional inflows.
Treatment	-	No treatment is modelled.
Invert Elevation	m	The invert elevation is extracted from the proposed grading DEM in PCSWMM.
Rim Elevation	m	Set at 0.5 metres above the invert elevation to allow sufficient depth for potential ponding which should be limited to 0.35 m.
Depth	m	The depth is internally calculated in PCSWMM as the difference between the invert and rim elevations.
Initial Depth	m	No initial depths are set at junctions in the model.
Surcharge Depth	m	No surcharge depths are set at junctions in the model.
Ponded Area	m^2	No ponded areas are set in the model.

G3.2 Storage

Storage nodes are used to represent minor system manholes, street sag storage and pond storage.

Parameter	Units	Description / Values
Name	-	Minor system nodes are named as per the design sheets, major system nodes are named as per the catchment draining to the node or as per the pond name. Manholes identified as 3XX in the EES model are nodes on the EES sewer network.

Parameter	Units	Description / Values
Tag	-	The following tags are used: **Tag** — **Classification** Manhole — BSUEA minor system On-Site_Storage — BSUEA major system street sag storage QP_Manhole — Quinn's Pointe minor system QPLow_Manhole — Quinn's Pointe minor system in the low lying area not draining to the ponds GB_Manhole — Greenbank Road minor system Wet_Pond — Wet pond storage Dry_Pond — Dry pond storage
Inflows	-	Minor system nodes in Quinn's Pointe have additional inflows which are hydrographs from the Quinn's Pointe SWMHYMO model representing the captured minor system flow.
Treatment	-	No treatment is modelled
Invert Elevation	m	For minor system manholes in the BSUEA and on Greenbank Road the invert elevation is as per the design sheets. For the EES model the invert elevations are lower than the design sheet to accommodate the simulation of the EES subdrains. For minor system manholes in Quinn's Pointe the invert elevation is as per the Quinn's Pointe detailed design XPSWMM model. For major system nodes representing street sag storage the invert elevation is approximate to the lowest point in the associated drainage area as per the grading plan. For wet ponds the invert elevation is the designed permanent pool elevation. For dry ponds the invert elevation is the base of the pond as per the grading plan.

Parameter	Units	Description / Values
Rim Elevation	m	For minor system manholes in the BSUEA and on Greenbank Road the rim elevation is as per the surface elevation of the grading plan. For minor system manholes in Quinn's Pointe the rim elevation is set at the nearest underside of footing. The rim elevation is therefore not the ground elevation and freeboard to the rim elevation should be a minimum of 300 mm. For major system nodes representing street sag storage the rim elevation is 0.5 metres above invert. For wet and dry ponds the invert elevation is approximate to the minimum surrounding ground elevation from the grading plan.
Depth	m	The depth is internally calculated in PCSWMM as the difference between the invert and rim elevations.
Initial Depth	m	No initial depths are set in the model.
Ponded Area	m^2	No ponded areas are set in the model.
Evaporation Factor	fraction	No evaporation is considered in design event analysis.
Storage Curve	-	For street sag storage Function storage curves are used. The storage is set at a constant area to provide 50 m^3/ha in 350mm depth unless otherwise noted. For manholes in the conventional system the Function storage curves are used. The storage is set at a constant representing the base area of a manhole for the entire depth. For EES manholes the Tabular curves are used. The lower point of the curve represents the storage in the EES subdrain and surrounding material for the lumped subcatchment draining to the manhole. The upper part of the curve represents the constant area manhole storage. For pond storage either Function or Tabular curves are used to represent the designed pond storage capacity.

Parameter	Units	Description / Values
Conductivity	mm/hr	In the EES storage nodes the seepage rate is set as per the results of the Paterson field testing of Hydraulic Conductivity. See section B6.1.1 of the Existing Conditions Report (Appendix B) for a description of how the saturated field hydraulic conductivity was transferred into infiltration rates. The values have been reduced by a factor of 2.5 as per guidance from the Credit Valley Conservation Authority and Toronto and Region Conservation Authority Low Impact Development Stormwater Management Planning and Design Guide Appendix C. The Guide states that a safety correction factor of 2.5 should be applied where there is a ratio between the mean measured infiltration rates of 1 or less. The safety factor represents the potential loss of infiltration due to compaction during construction and gradual accumulation of fine sediments over the lifespan of the BMP.

G3.3 Outfalls

Under the continuous simulation model two additional outfalls are placed to represent the outfalls to the groundwater receiving watercourses. These are not included below but are free outfalls with inverts to match the groundwater system.

Parameter	Units	Description / Values
Name	-	Outfalls are named either after the connection boundary condition manhole or as otherwise appropriate.
Tag	-	No outfalls are tagged
Inflows	-	No external inflows are applied at outfall nodes
Treatment	-	No treatment is modelled
Invert Elevation	m	For minor system outfalls the invert elevation is the elevation of the boundary condition storm sewer. For major system nodes the invert is taken from the grading plan.
Rim Elevation	m	For minor system outfalls the rim elevation is taken from the grading plan or existing surface. For major system nodes the rim elevation is either 0.5 m or 1 m above the invert depending on the connection conduit depth.

Parameter	Units	Description / Values
Tide Gate	-	No backflow is prevented in the model outfalls and therefore 'No' is selected.
Route To	-	If flow from the outfall is directed to another subcatchment but this is not done in the model and this parameter is left blank.
Type	-	Major system outfalls are free outfall nodes and minor system outfalls are fixed to the 1:100 year HGL in the minor system.

Conventional System 1:100 year 3 hour Chicago Output
